Part 1 never made it to info-atari16 when I posted it together with
part 2. So here it is.

This is part 1 of a 2 part posting of ARXX. I wrote ARXX because my
version of AR68 was unusable to make own object libraries for use with
LINK68. AR68 could list the contents of a library and extract modules
from the library, but replacing and adding new modules did not work
correctly (e.g. all module names were converted to upper case when adding
to the library, while extracting forced names to lower case -> impossible
to extract modules you added yourself). Below you will find ARXX.DOC and
an example of the output of the -tv option (list contents).

Part 2 will consist of the uuencoded ARXX.ARC containing the sourcefiles,
the program and ARXX.DOC. So if you can use it you only need part 2.

Some things I found out while writing and testting ARXX:
- stderr in ALCYON C (=Toolkit C compiler) uses GEMDOS handle 1, as does
  stdout. So redirecting stdout in Micro C-Shell redirects both stdout
  and stderr.
- You can prevent redirection for the standard GEMDOS handles by using
  negative handles (word size). So writing to handle -1 is what I use
  to write error messages to the screen.
- Detecting if GEMDOS handle 1 is redirected can be done by using

  the GEMDOS FSeek function (trap #1, function $42). When asking for
  the current position FSeek always returns 0 when handle 1 is used
  for the screen. Otherwise it returns a number greater than 0.

Here follow ARXX.DOC and the output from 'arxx -tv gemlib'

------------------ARXX.DOC--

NAME

     arxx - an object library maintainer, replacement for ar68

SYNOPSIS

```
arxx -trdwx[v] [-ab opmod] lib mod1 mod2 .... [>file]
```

DESCRIPTION

With arxx you can create and maintain object libraries to be used with LINK68. It has been written as a replacement for ar68, which did not function satisfactorily.
In the command specify only one of the trdwx options. With the r option only one of the ab options may be specified. For details see below.

1. Listing the contents of the library:

   ```
   arxx -t[v] lib [>listfile]
   ```

   The t option will give you a list of the names and sizes of the object modules in the library on the standard output.
   When the v option is specified the global symbols for each module are also listed. Global symbols in the data segment are preceded by an '*'and external global symbols (common data, C external variables) are preceded by a '%'.

2. Replacing modules in the library:

   ```
   arxx -r[v] lib mod1 mod2 .... modn [>listfile]
   ```

   The library is scanned once and the modules are replaced in the order specified on the command line. When a module is not found in the library it is added at the end. It is possible to get the same module more than once in the library by specifying the wrong order.
   This is also the command to create a new library.
   With the v option the modules copied and replaced are listed on the standard output.

3. Inserting modules in the library:

   ```
   arxx -r[v] -ab opmod lib mod1 mod2 .... modn [>listfile]
   ```

   When you want to insert modules in the library use the a (after) or b (before) option (Only one allowed). This option has to be followed by the name of the library module after or before which the new modules have to be inserted.

3. Deleting modules from the library.

   ```
   arxx -d[v] lib mod1 mod2 ... modn [>listfile]
   ```

   Deletes the modules from the library. The modules have to be specified in library order because the library is only scanned once.

4. Extracting modules from the library.

```
        arxx -x[v] lib mod1 mod2 ... modn [>listfile]

        The library is searched only once to extract the modules
        specified on the command line. The object files are created
        in the default directory with the same names as in the library.
        If you want an other name and/or directory use the w option.

     5. Writing modules from the library to an other directory/file.

        arxx -w[v] lib mod >newfile

        This works the same as the x option, but only one module may be
        extracted. This module is written to the standard output which has
        to be redirected to the diskfile of your choice.

REMARKS
     Output redirection (necessary for -w, optional for the others)) has
     to be performed by the command interpreter. When using arxx as a TTP
     application from the desktop you are out of luck.

     When no v option is specified arxx performs it work silently (except
     for the t option). With the v option all actions (copying, adding,
     extracting, writing, deleting modules) are listed on the standard
     output.

Keywords: atari & batteries included

I bought my atari about 3 months ago. At the time I also bought DB one
version 5xxxxx. Last month at the atari expo I bought thunderversion 1.01,
which by the way these things work together. The application I'm using it
for is to keep track of my Grateful Dead tapes recorded on my Beta hifi.
The box is too small to hold all the song names. Thunder works well as a
desk accessory with it because you can abbreviate the song names and have
the program expand them.

Anyway, both these pieces of software were outdated. I called up batteries
included. They said no problem. Your version is early enough to require a
free update just send your disk in. I tried to call up Stoneware for DB
one. They could not be found, even by address. I then called up Atari and
found they had the rights to distributuion of the product, but didn't have
the rights to update the copy. They said Stoneware offered the update for
25 dollars a while back. They could not even tell me if Stoneware was still
in existance. One, can you imagine spending 25 dollars for an update of
something I could buy for 34 dollars? Two Atari didn't seem to know what
the hell was going on with something they were in control of. I don't know
I just don't know.

Marty--

Several of us at work (and home) have changed word processors recently from "1st Word" to "Word Writer ST", by Timeworks. It may be short of the next-generation word processors that we're waiting for, but here's some of its features:

1. Pull-down menus.
2. Integrated 85,000 word spelling checker. Checks a word at a time, an entire document all at once, or continuously as you enter text. No info in the instructions on whether words can be added to the dictionary. Not as versatile as Thunder!, but pretty good.
3. On-screen special text: underline, italics, super- and subscripts, boldface, etc.
4. All of the other standard word processing features: cut and paste, find and replace, etc.
5. Editable printer drivers for many printers.
6. Reformats text by paragraph or by entire document reliably and easily. For example, change line length with mouse pointer at the top of the screen, reformat document: it works! I never could get this to work in 1st Word (maybe it was just me).
7. Ability to imbed printer control codes, which are hidden in the text on the monitor (but can be displayed by clicking on a check mark in the left border).
8. ASCII save to disk.
9. Up to 4 files may be simultaneously opened.
10. Easy out-denting (as this text is done).
11. Virtually all word processing commands are displayed in 3 rows on the bottom of the monitor screen. Typically one would leave only the lowest row showing (which defines the

10 function keys), but the text window can always be changed to a smaller vertical size to expose the other two rows. This greatly reduces trips to the instruction manual for info on infrequently-used features.

12. Number of pages, line count, word count, and free RAM displayed on demand.
13. Hard drive compatible.
14. Outliner capability with up to 5 levels.
15. Integration with Data Manager ST and Swiftcalc ST, also by Timeworks. Data Manager ST seems to have data graphing capabilities that go beyond those of V.I.P., but otherwise we have no experience with these data base and spreadsheet programs.

We like it. I recommend it for consideration as your ST word processor. I have no affiliation with Timeworks, or anyone else in the computer or software industries.

Summary: htb.uuencoded: email if wanted

[]

Due to repeated requests, I have uuencoded HTB.PRG (the program
that converts from hex-dumps to binary, ignoring comments (anything
from '*' to end of line).

To lessen traffic, email me if you want it and I'll send it.
(I'll post it on mod.atari16.sources (or whatever it is) once somebody
tells me how to get onto that...)

>You have two choices here: one buy the new XEP80 80 column adapter device or
>two, buy software that allows 80/132 wide screens (with horizontal scrolling).

You just destroyed your original argument: that IBM's were bad things because
you had to buy add-ons all the time, and that you didn't have to do that
for Atari 8 bit machines...

>>   But what about the capabilities as a microcomputer, you ask? Well, the
>> IBM has the 8-bit beat here, too. Say you want to hook a standard printer

>printer or whatever.

And how many companies do you think make/support serial (RS232) printers
as opposed to Centronix style parallel printers...?

>And trying to find cables to connect a IBM into anything
>as simple as a Epson printer can be just as much a pain. I have an easier time
>locating Atari cables then IBM cables unless I go to mailorder.

Are you serious? The Centronix parallel cable with a DB25 connector has
got to be *the* most common cabling connection available...

>> And speaking of software, the IBM has just about every micro I know about
>> beat cold in both public domain software and commercial software, in both
>> quality and quantity. That may be only because of the perceived usage of
>> the respective machines, but frankly, I would not even *think* of trying
>> to market a serious program for the 8-bit Atari, if only because of what
>> I know about the, um, "habits" of local Atari users with regard to software
>> piracy.
>I think that there is as much public domain software out there for the Atari 8

>bitter as there is for IBM.

...um, again, I ask: are you serious? Atari 8 bits may have a lot of software, but nowhere near the about IBM PC/XTs do. There is a book published that lists useable PD software for the IBM, sources, and where to find it. It is 1210 pages of very, very tiny print...

> And the software that you buy at the dealer (read:
>commercial software) is a heck of a lot cheaper for Atari then IBM. Although
>they are getting closer!

Well, that's true. IBM software has always been *way* out of line, because IBM knows there are a lot of niave people (and business people) who will, and have been, pay for it.

>> There's a guy who gets pissed when, for example, Analog states
>> that there isn't much Atari software because of piracy, but who has a
>I agree that piracy is deplorable, but I doubt that anyone does not have some
>pirated software.

...excuse me?

> My feeling is that if it is still available at the dealer,
>then you should pay for it. (Dealer being anything from your local computer
>store, to mailorder, to the publisher of the software). But, and this is a big
>but, if it no longer is available anywhere legitimately, then I will used a
>socalled "pirated" copy.

Yea, and if I want out-of-print books, I usually rip them off from the library, rather than looking for them in used book stores...

> This generally applies to games, as they seem to be
>the most pirated software. I don't think that I have ever seen real useful
>software pirated (ala Syncalc, SynFile, etc.), these are currently available

>of CAD available now for the XE (albeit somewhat crude). So I say that the
>XL/XE series are just as useful in business as the ST (unless you really need
>the .5 -- 1 Meg of memory). [And the 130XE can be pumped up to 1 MEG if you
>need it!]

Give me a break! So, try writing/using something where machine precision counts...it should be, for instance, relatively easy for an 8-bit computer to miss connecting the lines of a triangle, because the calculation had

a huge precision error in it. Or, in large business applications, how much of a spread sheet do you think you could fit into 64K or 128K? The real world has more uses for a computer than balancing checkbooks...

>
>> Short digression: Owners of 8-bit machines can take that as snobbery
>> if they wish (somebody always does, regardless of how tactfully it's

>> using most of today's 8-bit offerings for the kind of things I do, both
>> here at the office and while "playing" at home.
>Not snobbery, but your only advantage is memory and possible IBM
>compatibility.

...sigh...

Don't get me wrong, but I have both an IBM XT and an Atari ST. The ST is superior to the XT (even though I have the XT "suped-up") in almost every way, shape and form. But if you believe that any 8 bit machine is every bit as useable as a 16 bit machine, you must not use the machine for anything more than hobby computing...

...and if that sounds snobbish, I apologize...but I think, per chance, that it is true...

Can somebody tell me:
    What company is underwriting Atari's stock offering?
    If the offering is an "all or nothing" issue?
        If yes, what is the deadline for the 4.5M units?
    Whether the units include warrants?
        If yes, what price does a warrant get you and for how long?

Gemdos function 0x20 is the one you want:

Call: Super(stack); - or -   gemdos(0x20, stack);

where "stack" is a pointer to your supervisor stack or NULL (0L) if you
want to use the user stack as supervisor stack. The function returns a
pointer to the old supervisor stack. You MUST restore the stack to this
value when you exit supervisor mode or else the machine will crash.

C code example:

```
    long    old_ssp;        /* old supervisor stack pointer */

    old_ssp = Super(0L);    /* enter supervisor mode, use the user stack*/

    /* your super code goes here */

    Super(old_ssp);         /* exit supervisor mode, restore stack */
```

Assembly example:

```
    clr.l   -(sp)       ; pass a long zero (use user stack)
    move.w  #$20,-(sp)      ; pass gemdos function 0x20
    trap    #1              ; enter supervisor mode
    add.l   #6,sp       ; clean up the stack
    move.l  d0,old_ssp      ; save old stack pointer

; your super code goes here

    move.l  old_ssp,-(sp)   ; pass the old stack pointer
    move.w  #$20,-(sp)      ; pass gemdos function 0x20
    trap    #1              ; exit supervisor mode
    add.l   #6,sp       ; clean up the stack

Yesterday I discovered what is apparently already common knowledge:
that I/O redirection in the Beckmeyer shell and Lattice C do not work
together.  I called the friendly people at MetaComCo and they said that
yes, a patch exists, but no, they didn't have it.  They suggested
Compuserve.

Can some public benefactor who has access to the patch (assuming one
exists...) post it to this net?

What do people have to say about compilers? I have heard that Lattice is slow and that it produces code that is slow and large. It is, however, the compiler I am most familiar and comfortable with on other machines, and I like the use of the ANSI standard. How off the beaten track are other C compilers with regards to their libraries and the ANSI standard?

Also, being quite new to the ST (and 68000) scene, what about linkers? I have not heard of any independent linkers (a la phoenix plink86 on the MS-DOS machines), so I assume you get a linker with your compiler: but are there any standards with object code? If you buy a compiler from one vendor, but prefer the abilities/speed of a linker from another vendor, is it at all likely to be able to mix and match? On the PC side, all three of the compilers I am familiar with (Microsoft C and Pascal, Lattice C) will work with both of the linkers I am familiar with (Microsoft link and plink86). Does this situation obtain on the ST as well, or is there less standardization of object code format? Are there any standards in general on 68000 machines?

    thanx,

                                        JJMG

Right after I flamed at Antic, my package arived with a letter from
their customer service manager apologizing for the delay. Enclosed
with the letter was a gift certificate for $10.00 towards the purchase
of any AP or ST software from the catalog!

I guess Antic really does care about their customers.

 [For the great stone-eating mons..]

I'd like to thank all the guys who helped me out with the problem of order of execution of files in the AUTO folder; I got so many replies that it'll be better to acknowledge them all at once. Thanks! (The answer, as explained some days earlier by a poster, is that the files are executed in the order into which they are introduced into the AUTO folder). Now, on to the next question: (!)

I would like to get my ST into a certain configuration at bootup - into a shell, with a certain filestructure in my ramdisk, etc. I've been doing this by putting the ramdisk program and the shell program into the AUTO folder, with a profile (for the shell) that copies stuff into my ramdisk, etc. etc. However, this causes the desk accessories to not be loaded, because that seems to be done *after* the stuff in the AUTO folder finishes, so in my case only when I quit the shell. Now I would very much like certain desk accs. to be pre-loaded, so that I can do quick trips from the shell to the desktop, *without* waiting for the accs. to be loaded. This is also important because some stuff I use depends on the control panel to initialize the RS232 and printer ports.. Is there some way of putting a *desk acc. loader* into my AUTO folder, which would load the accessories? To prevent TOS from trying to load them when I quit the shell, the accs. could be renamed, eg. to .ACS or something. Does such a utility exist? I'm not sure what would be involved in writing it. I'd greatly appreciate any tips on this matter. Thanks in advance,

-ravi

>
     Actually, the problem wasn't monochrome, but some kind of conflict
with the 512K RAM Disk I was using on my 1040ST. It's definitely the
presence of the RAM disk since it makes no difference whether I run from
the floppy or the RAM Disk. It doesn't work either way. If I boot without
the RAM Disk, 'alite' works fine.

     One simple question. Approximatly how much $$? I am a simple mortal
and personaly object *VERY* much to being forced into buying a C compiler to
do development on the ST when all I need is the DOCUMENTATION.
     As a contrast, may I bring up that *OTHER* company.
     When Apple had similar complaints, they brought out a "promotional
version" of their Inside MacIntosh handbooks for those who didn't need the
entire developers package. How 'bout a similar deal for ST users??

Did you hear of the recent PSION-CHESS program for the Atari ST?
This is a completely new program developed by Richard Lang. It uses
heuristic search instead of the alpha-beta-procedure. This means that
the program can examine the game tree to arbitrary depth. It uses a highly
selective search to investigate the interesting lines of play. Moreover
its playing style is very aggressive. The search concentrates on lines
of play which are tactically sharp and which force the opponent to play
in a way which can be easily predicted. So not necessarily the best
move is played but the tactically sharpest with reasonable outcome.
This means that a depth of up to 20 plies can be forced and a gain of
material in let's say 8 plies is recognized.

The program can display up to 8 plies of its current expected moves.
There exist two ways of displaying the board: 3d and 2d. You can set the
board to an arbitrary position and there exist levels of play from
novice (1 sec) to expert (same time) and infinity. Also there are
problem modes for forced check mates. The program normally 'thinks'
while its opponent has to move, but with the feature 'handicap' this
can be disabled. A lot of other features are supported which could be

mentioned.

It seems to me that this program is identical to the Mephisto Munchen
with Amsterdam-modul since that one also uses the same strategy, the
same processor and is also by Richard Lang. If true that would mean
that PSION-CHESS alias Mephisto-Munchen is the recent world champion
of microcomputer chess (championship in Amsterdam fall 1985).

Has anyone further information on this program or on its strength?
I am particularly interested in the new programing approach realized
in this program. There exist some articles by Larry R. Harris about
heuristic search in chess, but these articles date back to 1975.
Are there other available programs which use the new approach?

One disadvantage to the method mentioned in the abbove-referenced message is

that each encoded byte transmits only 4 bits of information.

By comparison, uuencoded data transmits 6 bits per encoded byte, obviously 50% more for your money.

The problem with uuencode is that it uses certain troublesome characters such as spaces to encode data. This problem would be immediately eliminated if we were to revise uuencode to use only non-troublesome characters. For example, the set a-z, A-Z, 0-9, and . and / or any other set of 64 noncontroversial characters would do the trick. However, it would make programming simpler if the selected characters were in two contiguous ranges, such as a-z and 56789:;<=>?@ plus A-Z. (I think that adds up to 64 of 'em!)

I am considering the purchase of an Atari 1040ST
for use in a ham radio station. The ST looks impressive
but does anyone know whether it generates a significant
amount of radio frequency interference (RFI)? Will
the machine itself be vulnerable to RF? In short, how
will it perform in an RF environment?

I just noticed that a local computer store has Degas Elite for $79.00.
I thought I remembered that Antic or somebody had said that regestered
owners of Degas would be able to upgrade for half price or at least get
some type of discount. The local store hadn't heard of this (no big

surprise). Does anyone know about Batteries Included's policy?

Secondly, is there a Resource construction {set, editor} that can be used with Lattice or Mark Williams C?

Finally, has anyone developed an accessory that allows you to load and unload other accessories yet?

Hi... File capture doesn't seem to work in the new version of UniTerm.
When I start file capture using alt-C, the dialog goes through fine, but
nothing that I type or the remote machine sends back gets echoed on the
screen (i.e., the screen just goes dead until I stop file capture). I
can see something is getting transferred because the cursor flickers.
After stopping the capture, it comes back to normal. However, the capture
file doesn't have ASCII data in it (when I type it on the screen, I get an
-- END OF FILE -- message right away) even though the file length looks
ok in the directory listing.

Has anyone else encountered this bug or knows how to fix it? For the
time being I've gone back to using the old UniTerm since I use the file
capture feature. I would appreciate it if someone (Simon?) could send
me a fix.

Another question: What came of the terminal lockup debate? I ran into
this problem yesterday while using UniTerm. Has this been tracked down?

-- Ashwin.

UUCP: {decvax,linus,seismo}!yale!Ram-Ashwin
BITNET: Ram@yalecs

P.S. A suggestion: If you called DEFAULT.SET something like UNITERM.SET
or UNITERM.OPT instead (like Kermit does), all the UniTerm files will list
together in the directory listing, making it easier to copy them all to
RAMDISK in one stroke (rather than having to hunt for DEFAULT.SET at the
other end of the directory listing).

APL for the Atari ST

I have had my copy of APL.68000 for two weeks now, and am pleased with it. APL.68000 is a complete implementation with enhancements that make use of many of (and allow the user to make use of) the special features of the ST, like dialog boxes, alert boxes, function keys, line graphs, and pull down menus.

This APL has followed the lead of IBM in several ways. For instance, when APL.68000 first appeared, (some years ago), it included a copy of the IBM manual "THE APL LANGUAGE", and added a few pages about their own enhancements, such as the quad-SS function for string substitutions. A delightful feature is the use of the ALT key to provide access to all of the composite symbols. For example, the transpose symbol is traditionally created by typing a circle, a backspace, and a backslash. On the ST, I now press the ALT key and the "6" to get this effect. A set of keyfront stickers is included to show the mapping. This keyboard convention is not new. It seems to be the one that is used on IBM 3277 and 3278 terminals when used with APL and APL2, and it has also been adopted by other APL's such as WATCOM APL for their most recent version for the IBM PC and (I think) by STSC as well. A significant improvement indeed over the old way of composition.

The ST release is version 1.0, but it is release 6.0 for the interpreter itself, which has been around since before the IBM PC was introduced. I have yet to find any bugs in the APL. There are a few things about the interface to special ST features that I have not been able to do yet, that I would like to do. For instance, I would like to be able to read *any* key under function control, and I can almost do this, but not quite, because there seem are a few key sequences that are mapped to the same byte. For instance, reading the keyboard, I get the same byte from the HELP and the UNDO key. I would also like to be able to tell the "2" above the "W" from the "2" on the number pad. This would allow me to write a panel with special meanings for the keys on the number pad, while keeping the ability to have numeric entry.

The APL features a very nice "session monitor" that allows me to re-execute any line on the screen. It works like this: move the cursor back to any previous line, modify it (however I like), and press the return key. The modified line appears at the bottom of the screen and then it is executed. One aspect about this that I would change is this: I would like the previous line to pop back to its previous state, and then display and execute the modified line at the bottom of the screen. As it is, the previous line stays on the screen in its place, in the modified form.

The screen memory seems to be 75 lines long, and is controlled by the mouse in the side-bar.

There are two file systems available to the user. One is accessed by a set of supplied functions, with names like STCREATE, STREAD, STWRITE, and so on. With these, you can read and write ordinary native files. You can write any byte you choose, as many as you have room for on you disk.

The other file system is a sophisticated APL component system, complete with multiple user access control facilities. Imagine, if you will, a number of STs connected together, and that you might like to share some information with me, and something else with a third party, but each of us should not be able to read the other's components. Well, the hooks are all there. Until this comes along, a component file system is a marvelously usefule thing just for one person to use. One component can hold a character array, another can hold a numeric aray, another a Boolean array. You read the component, you get the array. You can replace the contents of any component with any other APL object.

I was easily able to make use of the native file functions and, with about 10 lines of code, write an "script" function that kept a copy of *all* my APL input lines, not just the last 75 lines that appeared on the screen.

There is a full screen editing feature at all times. There is a quad-R that displays the last input line, which you can then modify and execute with the press of the return key. If you prefer, for the entry of conventional text, for instance, to use the conventional typewriter layout with lower case, upper case letters instead of upper case letters and special symbols, you can easily switch. There is also a function editor that will feel comfortable to users who have become accustomed to ST mouse features.

The function keys are programmable from the keyboard. One of the first things I did do was to program one key and give)WSID,)FNS,)VARS, and)SI . I wrote a little function called EDIT that accepted a character string, the name of a function, which then programmed another key so that pressing it would open and display the named function.

I created an experimental a PANEL system. It is clear from the experiments I did that full control is available. I could dynamically change the meanings of the function keys, or, in fact, set some

predetermined action to happen at the stroke of any single key, and
then at the end of the PANEL session, set everything back the way it
was before.

On my 1M machine, with some modest desk accessories, I get a workspace
with about 600K. When I added a 500K ramdisk, I got a 100K workspace.

The documentation is complete. There is a fat manual telling all about
APL, a supplement that tells about special features for the ST, and a
pocket guide with brief summaries of all features.

I am pleased with APL.68000 on my ST.

In the US, readers can get APL.68000 from the Spencer Organization,
Box 248, Westwood New Jersey 07675. In the UK and elsewhere, it is
available from MicroAPL Limited, Unit 1F, Nine Elms Industrial Estate,
87 Kirtling Street, London SW8 5BP.

For those of you who ain't got much luck with UUDECODE and may happen
to be on a CDC system. I will send anyone who asks me a copy of UNITERM.ARC
in NETENC format which can be decoded with NETDEC which is available from
the file server at CYBSER@CADIA.

Keywords: Printer driver Epson 24-pin

I have a new Epson LQ-800 24 pin dot matrix printer and am trying
to use it withe the Atari 1040 ST.
I have installed one of the Epson drivers provided with First Word.
Text work fine but screen dumps do not work.
Screen dumps do not seem to do line feeds.

Does anyone have a printer driver for the LQ-800?

Subject: IBM Compatibility

Situation: Computer-less, but interested in the 520/1040ST. I also do all of my work, recreation, finance, etc. on an AT&T 6300+, which is highly IBM-compatible, but faster than an IBM-AT. I also spend a lot of time on the mainframe for school purposes. I'm definately going to want a modem, as I've had a lot of fun with a friend's modem and CompuServe and Dow Jones. I also want to expand my horizons into graphics, thus my choice for a 1040ST. I've heard of problems with expanding the 520 to 1M...

Queries: So then, I've heard a lot of talk around town, as well as on this BBS, about an IBM emulator. Rumors float around about it being 98% compatible, fully compatible, out in May, not out yet, not worth its weight in beans, etc. So what's the scoop? Living in Pensacola, Fl, I don't get to any conventions, and the dealers here couldn't find their asses with both hands and a flashlight, so I'm really just looking for information. Dealer's addresses for mail-order firms would also help. I've heard a *lot* of good things about 47th St Photo, but do they deal mail-order? And what's their number, to place orders or get info? Rumor also has it that Antic(?) has an emulator out. I read Neil's comment on Atari's emulator that's coming soon, but what about this one?

Another Query: A Hayes-Compatible modem. Are there any? What's the best one? Where can I find the best price? Etc. I'll want to dial up to our mainframe, but only at 1200 baud, since that's all students are allowed. We won't be connecting direct, so terminal emulators would only be necessary if they accept data at 1200baud

And Another: Software. I don't like paying thru the nose for it, which was one nice thing about the 520ST over anything IBM, is the availability of lower-priced software. And although I don't promote such actions, copying software is something that is done, and might actually help keep software prices down; my reasoning is that software companies would lower prices so that people would say "well, I won't copy it because it's cheap enough to buy." I know that's been the case with myself, when I bought TURBO Pascal. I wouldn't even think about getting Lattice C, for how many hundreds? Which leads to this...

What's the software situation for the ST? Public domain? Top software firms like MicroSoft? What's the scoop? I haven't had any experience with accessing public domain software for the PC, but then I don't have my own PC, or a modem for those that I work on. I've been watching this forum for some time, and see a lot of people posting code or portions of code for public use. This is great, but how would I get these files down to my 1040ST?

As you can see, I'm fairly ignorant into the workings of the ST's but want to learn. I've also just begun to learn about networking, and love it, but know little about file transfer protocols and methods.

Please everybody respond. I'd like to get as many various amswers as possible, including flames on my software copying opinions. I am on the list, so lets get everyone in on this. Neil, do you have a standard blurb from Atari on this?

Did anyone in the UK get a working copy of UNITERM? I'm told that it
was distributed in 4 parts, but we saw none of these. If anyone has it
and would be willing to send it to me, could they please let me know by
mail? Did this program, which everyone says is very good, actually reach
Europe or the UK?
     Martin

PS.
     Apologies to those outside Europe, to whom this may not be
very interesting.

To get the upgrade send your original Degas disk and $40 U.S. or
$50 in Canada to BI. Degas Elite sells for just under $100 in Canada,
and Degas for about $55, so the upgrade is about half-price, and the
total cost is comparable to the new cost.

For those of us who find it difficult or impossible to download and
uudecode files sent over the net, can someone upload them onto Compuserve?
I have found some info-atari16 stuff on ATARI16 (on CIS), but have not seen
such goodies as Uniterm. Upload time is free on CIS!

This would be a great help to those of us on BITNET whose IBMs like to
trash atari/amiga/vax/unix network mail.

Thanks,
maroC ddoTodd Coram

What version is the update? I recently bought Megamax C and received
version 1.1. Unfortunately, I have nothing to compare it to for
differences. If you have code containing examples of bugs in release
1.0 I'll be happy to compile under 1.1 and see if anything got fixed.

Send your original Degas disk to Batteries, Inc. with a check for $40.

>Finally, has anyone developed an accessory that allows you to load and
>unload other accessories yet?

I would love to have one as changing from low to medium res destroys
accessories and sometimes I want to swap accessories. I remember
a discussion about not being able to delete single ones, but I would
not mind being able to load a bunch from scratch each time.

Just send in your original Degas disk with original label, a check for $40, and your registration card (if you haven't already done so). Mention in a short note that your wish to take advantage of the DEGAS Elite upgrade for the Atari ST.

I'm waiting with bated breath for my upgrade, I just sent in for it yesterday.

Xref: mnetor net.micro.atari8:534 net.micro.atari16:2824 net.micro:6334

I was called to task for not mentioning OMNIVIEW. OMNIVIEW has been available for a couple of years and works with 3 wordprocessors: Atariwriter Plus, OmniWriter and Letter Perfect and a database: Data Perfect and a new communications program: OmniCom. OMNIVIEW is distributed by CDY (David Young) and is a true 80 column adaptation for the Atari 8 bit machines. Furthermore I was informed that John Scrutch of Atari has made the statement that the XEP80 Atari 80 column board/device will not make it out by Christmas (apparently when originally announced last June, they stated it would be out by October). This last sounds strange to me (would Neil @ Atari care to comment?) as I saw a working model at the Atari exhibition here in Portland earlier this month. The indications that I had then was that it would be out soon. Not being able to take the box apart, I was not able to see the state of the circuit board, it may have been an early prototype. The mechanical aspect of it was production quality (case, cables, etc.).

Secondly, before I get many more blasts, I use both my Atari 8 bit machines and my IBM XT primarily for wordprocessing, secondarily for telecommunications and thirdly for spreadsheets. For both wordprocessing and telecommunications, the Atari is equal to or better than the XT. For the amount of spreadsheets that I use, the Atari is just as good as the XT, but I don't create spreadsheets nine yards wide with an infinite amount of forulas, etc. I still maintain that for general office type work (i.e. wordprocessing and light spreadsheeting) that the Atari 8 bit is as good as the XT. (Have you ever looked at the lettering that a color monitor IBM gives out? Huge letters with many layers of bland pixels!) The letters that Atarwriter Plus may be a little crude, but they are as readable as the XT, IN MY OPINION! I have not personally seen OMNIVIEW letters so cannot comment, I have seen Letter Perfect and PaperClip and they are all as legible or better then the XT color letters.

If you are extensively into programming (in c or other) then probably most of the comments that I hear are correct, the ST outperforms both IBM and Atari 8 bit machines. Certainly the ST is superior to the 8 bit for CAD. If we are going to get into a general micro discussion, however, I agree that we should switch to net.micro.

Does anyone know for certain if a 1040 will output a color composite
signal? I know a 520 will (I have a friend with a 520 who hooks it up
to a composite monitor), but my 1040 doesn't seem to output composite,
even though the pin diagram in the back of the 1040 manual indicates
that it should. I read a short piece in Compute's ST magizine that
said 1040's don't have composite, only 520's do. My dealer doesn't
know. Help please -- my monochrome screen is extra sharp & nice, but I'd like
to see FujiBoink at least once on my own ST.

Sorry, make that "blank" pixels -- anyone who has ever used an IBM color monitor will know what I am talking about. All Atari (ST and X-) are infinitely better when it comes to screen graphics (alpha numeric or other).

Summary: New way to code PICTURES - & problems

[]

By now I have a working AL RAM-resident program that, upon Alt-Help,
saves the screen in a file in a format that is BOTH compressed and
in a text (modem-able) form. Doing both in one algorithm
is not only convenient, it is essential for getting the most compact
final product. A typical desktop yields a TEXT FILE of about 7600
chars: 25% of the length of the bit map!

(Details on the coding algorithm used do not belong here,
It is similar to uuencode, but does not
use space chars nor is it sensitive to added/deleted control
chars or spaces.)

I am now working on a decoding program, to view such files, and on
a translator from the compressed format to Postscript (my intended
use of this whole mess is to send ST graphics to be printed on a
remote Laserwriter...). I'll post it all when done.

Problems:

The coding program (I call it scode, or perhaps sencode?)
works fine from the desktop, but hangs if Alt-Help is pressed inside
Micro-C-Shell. Why? (When first run, the program replaces the screen
dump vector at $502, then does Ptermres() to stay in RAM.)
(I also bite hard and do OS TRAP calls from my code, even though it
is called from the Alt-Help interrupt handler. I don't really have
a choice, do I?)

Also: At the end of the ROM screen dump routine, it has:

```
    ADDQ.L   #4,A7
    RTS
```

If I end my dump routine with the same or with just plain RTS, it
works the same. What's going on?

Any advice would be appreciated.

Could someone tell me if it is possible to redirect standard output to a file, and then chain to a program with its output dumped to the file. What I want to do, is make a GEM shell for the Alcyon C compiler along with build capabilities, to have a nice GEM c development package. I would like to have a way of grabbing any output from the program to check for errors, etc.

Code samples to do the redirection would be great. Is there any way that this will work? Do programs return error codes to the calling program? Thanks.

cat << \SHAR_EOF > readme

I'm opening myself for flames by posting this to the net, but I've had
over twenty requests for this simple program, so I'm posting it in
three parts.  This part contains source for the two uuen/decode
programs.  Part two contains the uudecode program in the "new"
uuencoded form.  And the last part contains uuencode in the encoded
form.  The new form is compatible with the old version as long as you
delete the character tables at the beginning of each uuencoded file
(they're the group of letters before the "begin XXX FILENAME.TTP"),
delete the "include UUDECODB.UUE" line from the end of UUDECODA.UUE,
and delete the "begin part b" line from UUDECODB.UUE.  Then concat
UUDECODA.UUE and UUDECODB.UUE and run through your own UUDECODE
program.

First, about the IBM emulator: there are currently only two that I am aware of (I would like to know what this ANTIC one is supposed to be). That is, the software emulation by Paradox, and the hardware one, as yet unreleased, by Atari.

(a) Paradox: obviously, software emulation is slow. However, it SHOULD be possible to get absolutely everything to work right, if you think of everything people will try to do. The programmer who wrote the emulator claims it will run everything, no exceptions, including the famous benchmark, Microsoft's flight-simulator. He says it is about 70% of the speed of an XT. He says he has it running on his ST with the PC files in a partition of his hard disk (!), that he has compiled and assembled a lot of stuff on it, using PC-DOS compilers and assemblers, and that the only place where it is really slow is in doing direct writes to the screen, since those have to be patched. Importantly, such direct writes are SLOWEST in text mode: graphics are much faster! This is because of course text writes simply involve poking an ASCII value into the screen memory, which of course does nothing on the ST (you have to find the bitmap of the character at that ASCII address in the font, and then plot that).

He insists, though it is a mystery to me how it can be true, that you can only run his emulator from one of the 5.25" drives they sell: NOT from any other 5.25" drive (i.e. you cannot for instance put the emulator startup on your hard disk: you MUST have the floppy to boot from). Everything else CAN go

on your hard drive, as I said above. I don't know how a floppy can detect what drive it is running on, frankly. He says they have a year warranty on the floppy drives, and mail-order they sell for under $200, which is good, assuming they are good drives, which the warranty would imply. The emulation software itself sells mail-order for about $40.

(b) the ATARI emulator has been demoed right and left, and some people claim to have SEEN it run the flight simulator at a 30% speedup over the XT. Those "in the know" say it has been about 95% compatible at past demoes. The emulator was supposed to be released in September. Then it was pushed back till after Christmas; now they are saying maybe not until Jan. The inference to be drawn from this is that if it was 95% compatible when demoed in Sept., they can only be holding it up in order to make it 99.9% compatible. In theory, it should be possible to make it as compatible as any clone. No one at Atari is willing to talk about it, nor can anyone find out whether it will come with a 5.25" drive. So that's a big unknown.

Secondly: modems. The Avatex has two versions out: the 1200 and the 1200HC. They both do 300/1200 baud, and both are Hayes compatible, with the former having an almost complete subset (lacking, prominently, the hangup command that would make it possible (a) to run a BBS, or (b) to dial up your computer from a remote site and then not leave your telephone tied up and impossible to phone again); the latter is 100% compatible. Mail-order, it is easy to get the former for about $80 and the latter about $130, w/o cable. Good prices! I have not heard anything bad about them (nor anything spectacularly good).

> you had to buy add-ons all the time, and that you didn't have to do that
> for Atari 8 bit machines...
>
Maybe I was not as clear as I should have been, yes, sometimes you have to buy add-ons for an Atari, or a Commodore or an IBM, etc. (Read open architecture or whatever you want to call it.) Add-ons for Atari are merely cable plugins for the most part. They usually do not involve taking your computer apart to add boards, flip dip switches, etc. Granted the early 400/800 was an exception -- but it was a true open architecture and for the most part all you did was add boards. What I was trying to say was that for the most part what I either had built in in my Atari or could add with a cable type plug in unit, is not true with the IBM XT that I use at work. The IBM requires not only that I add new cards but also that I often must reconfigure it either thru software or more often thru dip switches. Have you ever tried to figure out first of all where the damn dip switches are, secondly which one dip switch you want and thirdly which switch on the dip switch needs to be off and which ones need to be on? Believe me, it's a pain in the ***.

> >> again.
Cables for the Atari line are available in this area as readily or more readily then for the IBM and there is no difference between the 1200XL and any other Atari as far as cabling goes, the only difference is in the OS.
>
> And how many companies do you think make/support serial (RS232) printers
> as opposed to Centronix style parallel printers...?
This comment loses me, I use a centronix parallel style cable/printer port on my Tek 4107, IBM-XT and all Atari's. Granted for about $150 you can add a board to an Epson to make it serial. What is your point?
>
> Are you serious? The Centronix parallel cable with a DB25 connector has
> got to be *the* most common cabling connection available...
Probably should be, but except for authorized IBM dealers, it is not that common in the Portland area. Admittedly, the most uncommon cable to find is centronix to centronix. Recently tried to obtain 5 of them for some Tek 4107's and ended up having Egghead Software custom make some for us.

I won't comment on this as more informed persons on the net have already been countering this argument. There is some concern of quantity vs quality, and most User groups have a lot of each (Atari, or IBM user groups).

> ...um, again, I ask: are you serious? Atari 8 bits may have a lot of software,

Again, I only am aware of what the various user groups have available, believe me in the PNW we have a lot of PD software available thru the user groups. land Atari Club, Seattle Puget-Sound Atari Computer Enthusiasts, etc.)

> >pirated software.
> ...excuse me?
> Yea, and if I want out-of-print books, I usually rip them off from
> the library, rather than looking for them in used book stores...
I hate to push the issue, but where do you find "used software stores" and isn't it just as illegal to sell software as it is to copy it? I do not go out of my way to obtain illegal software, I try buying it first. In fact I do not ever deliberately obtain illegal software, but I am sure that I have downloaded software from a BBS that was. I just have no idea how to identify it as such. Software does not have a tag saying, this software is illegal copied software. How do you decide that what you have downloaded from a BBS is pirated and should not be used, but erased? My crystal ball does not read software for illegality. And again, I have never heard of pirated business type software, but am aware that many, many games are copied illegally. So I generally stay clear of games, but for my kids, I have downloaded games from BBSs and I have absolutely no idea what is pirated and what is legitimate. None of the game titles are familar from the software that I have seen at my local computer store. So before you get on your soap box about using pirated software, tell me how you figure out what is nice and what is pirated?

>   --- Rob DeMillo
My last comment is that I wish that Rob would go to one of the Atari Computer Faires now being organized on the West Coast (San Jose and Portland have occurred, but more are coming including Seattle). There is a form of Pascal for the 8 bit (Turbo Pascal) that supposedly is a full set (or whatever the term is) and there are CAD programs available now that work, look nice and do not have the mathematical errors in them that Rob seems to think. As for the ST, try looking at Real CADD from Generic Software (what a company name!)--it is exceptional for use on either the IBM or the ST, but the ST is super looking.

One other comment, since when is the IBM PC a 16 bit machine? I always thought of IBM PC (and XT) as being 8 bitters, also. I believe that the IBM AT is a 16 bitter, albeit not a 68000 chip.

--Bill Dippert--

Disclaimer: I do not have stock in Atari, Commodore or IBM, my opinions expressed are my own and do not represent Tektronix, or any computer vendor, manufacturer or supplier. And I definitely support the viewpoint of ADAPSO.

Somehow my great IBM XT lost a line or two in my previous transmission. The user groups that I referenced were: Portland Atari Club, Portland Oregon; Eugene (Oregon) Atari Computer Enthusiasts; and SPACE which I believe stands for Seattle Puget-Sound Atari Computer Enthusiasts. There probably are others also in the PNW, but these are the big three.

Right justification with proportional fonts in a printer is best done by the printer. You will have to find out what the escape codes are for setting left and right margins and for selecting right justification, and embed these in your text.

If your printer does not support right justification, it will be a real "bear" to implement, because the printer drive will have to know exactly how wide each character is.

47th St. Whatever (camra, stereo, computer, ???) is indeed into mail order. I don't happen to have their address or phone number handy, but they usually advertise in BYTE. So far as I know, they have an excellent reputation for low prices and solid service if problems should develop.

Another place you might try is Applied Computer Associates. They were, as of a few months ago, beating any legitimate price by $1. They had the 520ST for $495 as I recall. Their phone number is 1-(800) FOR-ATARIS (428-2747).
I have dealt with them as a walk-in customer and believe them to be a very solid place to put your trust in. Address is 16220 Frederick Road, Gaithersburg, MD 20877. (Southwest corner of Shady Grove Road and 355, for you locals. Local phone is (301) 948-0256.)

COMPUCLUB in Framingham, MA (617) 879-5232 seems to be run by good folks also. Tom Graziano is proprietor. INWATS phone is 1-(800) MY-ATARI.

Other places with very competitive prices are:

Computer Mail Order (I got good service from them on my one order.) 1-(800) 233-8950.

Black Patch Systems. 1 (800) ATARI02 (757-1302). Typically the BEST prices on everything. (But check on shipping charges, which I haven't compared with others.

Electronic One. (614) 864-9994. Good prices, no experience with them.

CSC, Hightstown, NJ. (609) 448-8889. Small but very helpful and competitive.

Re: 520ST 1M upgrade. This seems to be successful if done right. Several people on the net have had success, a couple of others have had problems. Several people do the upgrade commercially, including COMPUCLUB and Applied Computer Associates mentioned above. Price is around $140 to $150.

I hope this is of some help.

Summary: compact new modem ad

[]

I hope this is not too commercial...

I have an Avatex 1200 and am quite happy. But if you're still
shopping, I just got a catalog from Priority One Electronics
where they have a tiny thing (a wee bit larger than the usual
AC adaptor) that plugs into an AC socket and has phone and RS232
connectors on it. It is claimed to be a Hayes compatible auto-dial
auto-answer 300/1200 baud modem, complete with speaker.

I suppose that's one of the new modem designs using the new
1200-baud modem-on-a-chip chip. Expect others soon, and
probably price drops...

They sell it now for $129 (RS232 cable not included).

Their address is:

     21622 Plummer St.
     Chatsworth, CA 91311
     (800) 423-5922

But then, my Avatex 1200 has DIP switches for all kinds of settings,
and also has nifty LEDs and an on/off switch... - all missing from
that little thing...

A few answers/suggestions:

     Never put a function call inside a macro! E.g.: isalpha(c) is
a macro (defined in ctype.h):

     #define isalpha(c) (c>='A' && c<='Z' || c>='a' && c<='z')

which means that isalpha(c=getchar()) calls getchar() 4 times, probably
not what you wanted... (to make things worse, getchar() is a macro
inside another macro...). BTW, they should have defined isalpha as
above but with "(c)" instead of "c" everywhere - that may be why it
does not compile...

     To get stuff out on the screen or whatever, flushing the
buffer, use fflush().

     The Megamax malloc(), as explained in the manual, is designed
to bypass the problems with the OS Malloc(). It takes no less than 8K
at a time from the system, and does further splitting itself. It works
mighty fine under heavy use, with MANY small malloc()s and free()s,
as exemplified by my microEMACS.

     To print out a pointer, use:

     printf("%lx", (long)pointer);

(remember: from now on, pointers are 32 bits, until they get to be 64!)

- Moshe Braner

PS - anybody got the upgrade from Megamax yet? Or is it due Friday night?

At the risk of being repetitive:

     Before I shell out money for ANY piece of software, I find
out whether it is "copy protected". If it is, I DO NOT BUY IT!!!!!!!

FLAME ON:

I will not buy a car with that thin spare wheel and a 55 mph mechanical
limit, nor an insurance policy where other drivers are excluded.

I will not buy a book printed in ink that is visible only under a
special lamp.

I will not rent a house with limits imposed in the lease on guests
staying overnight.

And I will not pay for software that will not run off a hard disk,
a ram disk, and a backup.

FLAME OFF.

>More questions regarding shell escapes:
>
>In 3.7i, M-X ! prompts for a command to send to a CLI. It seems to do
>something, but not very useful.

The "shell-command" (^X!) in the latest version of ue3.7
seems buggy. If you try (say) ^X! then "make.prg" you get a bus error.
(Using MONST which came over the recently I found the bombing code
was caused by reading a NULL pointer) .

Strangely though if you first try ^X! then just <SPACE> you
get back to u-emacs and subsequent ^X! 's work properly !!

That aside this version is *REALLY REALLY* good.
(but I cant get the ^X# and ^X@ commands to work. are they supposed to?)

I've put 3.6 on our VAX as an alternative to VI for our users
 (It dos'nt give the load overhead that GNU emacs does!)
I'd like to put on 3.7 .
Any chance of a sources posting of 3.7 ???

I hope someone out there can help me. I am an Atari 8 bit user who
needs to upgrade to a moore powerful machine for proogramming purposes.
I have narrowed the field down to PC clones and the ST. I am wondering

if there are full ANSI versions of the major languages out for the ST, especially Pascal and Prolog. I know OSS makes both but I don't know how 'mini/mainframe' compatable these are. If I get an ST who can comment on which monitor would be better monochrome or color. I am mainly going to use the machine for programming and uploads/downloads to a VAX and HP9000. I understand that the internal drives on the 1040 are bug ridden. Someone please help before I make a big mistake and buy a PC just for the software.

Jon Jensen
Utah State University
Logan Ut
CS DEPT

P.S. I know the ST is a GREAT machine (so you don't have to convince me of that)

I'm not convinced that 'descriptions and mail to requesters' would actually cut the net traffic. At present (bar accidents) net stuff crosses the Atlantic once (to Holland, innit?), crosses the Channel once, and so on. A separate trans-Atlantic posting to each requestor would pretty obviously crank the transmitted bitcount right up.

Similar arguments, of course, apply to non-international posting. Also, I think that this net has a higher connectivity than 'pure user mail', so that solution would leave lots of people out, I spect.

Better, the idea (is it reelly going to happen) of a separate meeting for the software, so that them as don't want it can more easily miss it out.

OK, but which C is most Alcyon compatible? I tried to convert something
A->MM (the details are a bit fuzz now) having to do with trying to move
characters with a pointer into memory based on an offset and some index
in a loop. The problem was that Megamax complained that the pointer was
not the same type as the long int that was the calculated address.
Alcyon accepted this no problems. This was probably 'lint', but I couldn't
think of any other way to re-code it. Ideas anyone?

I dislike Alcyon for several reasons among which are:
1) Multi-passes, multi little bits and pieces contribute a lot to its slowness
2) The links are a MESS, in Megamax, you just point to the .O files you want
   linked together (yours not system stuff) and it goes. None of this
   fiddling with multitudinous libraries and worrying about what order...
But unfortunately, a LOT of good software around is still written in it.

The .O files are not compatible either!   That's not right. I wish there
was a standard ST linker, and that PASCAL, MODULA, and WHATever else all
produced the same type of object files, which could then be linked together.
I know that there's some different parameter passing conventions there, but
Am I asking too much? Why not?

So what about Mark Williams' and other Cs with respect to source compatability?
(The object file compatability is just a dream with multi vendors *sigh*)

Sigh. Someone up there doesn't want me to have UniTerm 1.5c. Our site finally received parts 1, 2, and 3 of the 16th (19th? it's scrolled off my screen) posting of 1.5c. Assuming that the part 3 I got earlier was correct (got it twice, and they both matched) the new part 3 was savagely truncated =678 lines, missing about 600 if I counted right. Part 2 ('A') was also chopped off short. So, I've now got

  Part 1 Read Me
  Part 2 ('A') 1 bad copy (truncated)
  Part 3 ('B') 2 good copies and one bad (truncated)
  Part 4 ('C') 1 good copy

Of course this all assumes that the Parts were all the same each time. Anyone with UK PSS or JANET access (or US ARPA) willing to trade a part A for one of my spare part B's :-).

  JANET: Smee at AUCC
  ARPA: Smee at AUCC via UCL-CS.ARPA

(in whatever syntax your favorite mailer uses for at's and via's)

The search terminators should be bindable (like the meta key). I have
to type ^3 (control-3) on my vt220 terminal for <escape> right now :-(.
I would rather bind the terminator to something else (like FN^N). (I use
sys V curses, so I can get 10 function keys and the cursor keys - .emacsrc
takes care of the rest).

We in terminal land don't have control-return, so I don't think it
should be used as a terminator. I bind the function "hunt-forward" to a
function key (1 keystroke instead of 2 or 3). (The backwards function is
"hunt-backward" (Before flaming, see item 4. - he can't RTFM)).

>4. Is there documentation available for 3.7i? I was thinking of the syntax
>of regular expressions in particular, but a brief description of each

>

Regular expressions! Gee - I wish - but then again, I only have 3.7 (from
mod.sources). Can I get sources (I suspect search.c is all that's needed)?
Better yet, could the pattern matching stuff goto either net.sources or
mod.sources?

Happy hacking!

That ---END OF FILE--- reply for your request to display the file is not uncommon. That *THING* that Atari put into GEM to display the file has got to be the most USELESS object on the ST. I hate asking for something to be displayed and having only the "printable" (according to WHO, an owner of a century old Teletype??) characters displayed (ever tried to dump a 1st Word file saved in WP mode?), and spurrious premature EOF's.

Request: How difficult would it be to case the SHOW|PRINT|CANCEL alert to branch to some DECENT file display. It should be able to set a DEFAULT for PRINT|SHOW (if it's fast you can always CANCEL from the display!)

   Even if that's too hard (with ROM), does someone have a fast SMALL desk assessory that displays (R/O edit) a file: maybe a window, that displays ALL characters using the full character set, displaying "unprintables" (0 - 1F) as, say grey "."s (I don't care) and the minimal set of pull/down or CNTRL key options or commands:
1) Toggle ASCCII|HEX
2) Toggle CR: use|display-as-glyph
2) Scroll bars + keypad arrows + ? (other movements)
3) FindUP, FindDown of arbitrary string (including ALT and CNTRL chars),
   terminated by mouse click, not ^M (unlike uEMACS), so you can look for CR.
4) Quit (UNDO key?)
But K.I.S.S. (and SMALL/FAST)

The thing shouldn't care if the entire file is 1M-all-one-line (unlike uEMACS which complains about too-long lines).

The only thing that I've found that has most of the functions is DiskDoctor but it's big, slow, and more than is needed.

Hi Neil:

I was in the store the other day looking at the Easydraw program, and I
was suprised to discover that GDOS is being distributed with this program.
Included with this GDOS were some fonts, device drivers, and a program named

OUTPUT.PRG.

After trying Easydraw I got a copy of PaintPro (Abacus) and tried running it. PaintPro simply would not run with GDOS installed on the system, but ran just fine when the system was booted without GDOS. The README file that comes with PaintPro claimed that it would work with GDOS installed. When the program starts the menus claimed that the Swiss font is loaded, but the program soon bombed. The salesman at the store said he had no idea what was going on.

This all disturbs me. Apparently GDOS is already being given away in some form with commercial software, but you are telling us that we are going to have to pay money for it. Will the GDOS given away with software in the future be the same thing that is going to be sold for money separately? Is it possible in the future that some old software will not work correctly with GDOS installed on the system? Do you have a date in mind for the "release" of GDOS?

Thanks in advance,

Karl

Due to overwhelming arpanet congestion problems and user complaints
of slow mail delivery on Score, INFO-ATARI8 and INFO-ATARI16 are
immediately being converted to a non-immediate distribution mode.

This means that you will probably not receive any ATARI mail at
all for several days, after which you may start receiving Digests,
rather than single messages.

Please do not send complaints - this is apparently the way that
it has to be. (though if any site want to take over distribution
of the list, that would be ok with me - INFO-ATARI is currently
maintained by a set of volunteers with a guest account on score).

Keywords: Magic Sac Mac Cartridge
Summary: Not Everything, but LOTS

In article <861028-163116-1001@Xerox> BillHolland.ES@XEROX.COM.UUCP writes:
>How about a update on the Magic Sac.
>
>Bill

     Hi!
     I've had the Magic Sac since very soon after it came out. Version
2.00 of the driver software is now available, and improves things somewhat.
     Do not get me wrong. Everything does not work on the Cartridge, and
if you have a specific program in mind, CHECK FIRST (mail me. I can probably
help you out.) The version 2.00 driver software cures the serial port troubles
that plagued the earlier version. I know of 2 terminal programs that work with
the Sac. Freeterm, and TermWorks. These are both shareware. ie. if you use it

pay for it. Both of these programs are faily simplistic, but do have good downloading capabilities. Unfortunately, Red Rider does not work.

Other software that works (or seems to!):

MacPaint, MacDraw, Redit, Edit, Finder (4.1 and earlier)
Basic, JoyPaint, ClipArt Effects, certain RamDisks, Font Librarian,
Iago (a game), Wizards Fire, Daleks II
Most DA's that I have found.

Major Dissapointments (didn't work):
ResEdit, Fedit, Wizardry (boo hoo!), Fortran (My transfer may not
have worked properly), MDS Assembler, Finder 5.3 etc, Rmaker,
MacWrite (Dave Small is working on this) MacWord.

Also note another shortcoming of the system. In order to easily use any printing functions of these programs, you must have either a working printer driver for your Atari style printer FOR THE MAC, or an imagewriter (this is by far the simplest way, but it is a pain to keep unhooking it from you Mac :-) In order to help alleviate this problem, I have written an Imagewriter -> Epson printer code translator. All I have to do now is hook it into the driver software. I'll let you know how it goes.

One Interesting Aspect of the Cartridge is that it gives you a chance to easily compare the software aspects of the two systems without having the hardware get in the way. As a rule, and to my own great surprise, I very much prefer running under GEM than the Finder. The Finder is *very* slow, requires excessive disk swaps given a one drive system, and takes forever to load in desk accessories when you need them. It does have a much more flexible memory allocation system, but you pay heavily for it in speed.

As for drop down menues vs pull down menues, this is *definitely* a matter of preferance (good religeous war topic!). I much prefer a well thought out GEM desktop arrangment to the Finders slowness. While I'm on the topic, does anybody know whether GDOS changes the GEM desktops features at all?

Anyways, Summary:

If you want to have access to Mac software, check first, but the Magic Sac is probably a good way to go. If you are looking for a more powerfull programming environment, check into a Good CLI before going to the Magic Cartridge.

Thanks for reading my wordyness
Pete

[]

I'm not very sure, but I think that the terminal lockup happens
when a ^S (X-off) arrives from the host, and the atari (fully
compliant) stops dead waiting for a ^Q. The ^S could be due
to garbage, in which case, people have to re-boot or whatever.

In my case, running PC-Intercom, I find that resetting the
terminal, or simply typing "<UNDO> n" does the trick.

It drives me mad to see that people don't dare to post useful (or at
least interesting) material, while literally everyday 100s of KBs of
trash flood the net. Post your *.sng/*.pic combos.

I'd agree with Ken Thompson. uuencode may not be great, but it is usable --
sometimes with a little thought using inspiration derivable from the
uuencode doc. And, it is more-or-less standardly available on Unix systems.
If we invent a new encode decode technique, I foresee continual requests from
new people joining the net for yet-another retransmission of fredcode -- or
whatever it's called.

From this standpoint, even hex encoding is optimal, as it is obvious when
you see a hex file what you should do to unpack it. I fear new baroque
and clever coding techniques will cause more confusion than they solve.
(Unless, of course, you can manage to get the new stuff packaged in as a
standard bit of Unix systems.)

(Also, a quick comment on the original version of the proposal --
The character set A-P is only contiguous on ASCII machines. Fine for
my purposes, but not that handy for EBCDIC users. Of course, I've been
known to argue that EBCDIC users deserve whatever they get, but I'm
prepared to accept that others might disagree; and besides, it's not clear

there *is* any nice subset of chars in EBCDIC.)

I copied Rogue over to my hard disk, and it runs fine from there, although
it requires the original disk in 'A'... it just accesses it for a couple
of seconds. Also, you can only save files to the original disk! But at
least the loading time is slashed, especially for those l-o-n-g picture
files.

Keywords: Epson MX100 screen dumps
Summary: That's one small step for an IBM, one giant leap for OKIData/Epson

[Pacman lives]

Sounds familiar... I bought my atari, soldered up a parallel cable for my old OKIData Microline 92 which was formerly speaking RS232 serial, tried to print some things, swore a little, flipped some option settings, etc. After I got the basics to go, I tried a screen dump and got the same results as you did (looks like blank bands between each print pass).

I didn't have a better way to view the control stream, so I put the printer in low-res mode for 480 bytes but gave it no data, and then started a screen dump. Decoding the pixel patterns, I found the following ugly sequence at the end of the first line of graphics data (I don't know about the other lines, but I assume they're the same; they *LOOK* the same):

```
ESC '3' 1 (theoretically, advance in 1/216" increments)
LF        (OKI/Epson stepper can only step 1/144", so does 1/144")
ESC '3' 1 (beats me why they do it again)
LF        (another 1/216" (IBM) or 1/144" (OKI/Epson))
LF        (and another)
ESC '1'       (set 7/72" mode)
LF        (travel 7/72" (everybody))
```

(The 7/72" mode is correct, but I'm working from memory on the ESC '1' code, so that might not be the correct character sequence.)
This whole mess is supposed to advance the 8/72" height of the print head. The stepper motors for the OkiData (and, I guess, the Epson series) step in 1/144" steps instead of 1/216", so the printer goes 1/144" on a 1/216" request to avoid the problems of not spacing at all. The problem is that after three 1/144" steps, we've gone 1/144" beyond 3/216" (1/72"). The printer corrects advances of 3/216" steps to 2/144", but it doesn't have the smarts to correct them when they come 1 or 2/216" at a time.
If the 1/216" section had been replaced with

```
ESC '3' 3
LF
```

the problem would not have shown up (at least in screen dumps).

I have a call in to Atari to see if they already have a simple solution to this (besides buying an IBM printer). If not, I wrote an algorithm to correct accumulative and local error on the fly. If Atari doesn't have an easy answer, I will also write the code to insert my algorithm between

the BIOS trap vector and the lst: output routine (it's an ugly scheme, but
what can you do when your *OS is in ROM?).

Anyone who is interested in the results should send me mail. If I get a
large response, I'll post them.

I am considering purchasing an ST and hope to do my own programming to
use the MIDI ports. Can anyone out there in net-land tell me about
using the ST with synthesizers and the like? I am a musician as well
as a programmer and would probably want to write a lot of my own software
for sequencing, voice editing (specifically Yamaha DX7) and the like.

What is a good language to use? I assume C is the best, but which one?
Can Megamax C be used with the MIDI ports?

What about this MacCompatible cartrige that is rumored? Will Mac MIDI
software run with the ST?

As you can tell by now, I know very little ST programming (I have an old
atari 800) but I would like to get into doing music with the ST.
The ST is the best machine for me since I would want to get MT "C" Shell
as well (I'm also a UNIX hack).

If anybody knows anything about ST MIDI software, I would appreciate any
responses either over the net, or by e-mail.

Thanks much,
     Mark Milbourne

It seems unlikely that the critter will run, since the desktop
and AES have not been initialized at the time \AUTO folder
execution takes place. Doing an AES call from an AUTO program
will likely result in a crash ->thud<- and an endless cycle of
reboots. Life is like that sometimes.

<><><><><><><><><><>
I am having problems running certain write-protected programs on my 1040.
I checked the speed of the internal drive (using a program from one of
the BBSs) and it was 304.5 rpm. My external (SF314) drive was 301.5 rpm.
What is the correct speed (300 rpm?), and how do I adjust it?

     Thanks,

>    }
> }
```

The problem here is the Fclose(fi) --- you can't close a handle, even after an Fforce, because handles in GEMDOS are shared between ALL processes. [In theory, you could open a file, do a Pexec(), and have the child process do I/O on the handle that the parent opened. In practice, this is a bad practice....]

Negative handles correspond (kind of) to BIOS devices, -1 is CON:, -2 is AUX:, and so on. Handles from 0 to 5 are "standard" handles, and are inherited by the child on a Pexec(). Handles 6 and up always refer to files. Standard handles are a kind of indirection; they "point" to a character device (handle < 0) or a file handle (> 5).

          status = Pexec(0, "program.prg", tail, (char *)NULL);

     where :-
     program.prg : should be the complete pathname, including extention.
     tail :
          tail[0] = length of command tail;
          tail[1...len] = Command tail (args) '\0' terminated
     (char *)NULL for the environment means that the child process
               inherits the environment of the parent. if you want
               to pass an environment, it is of the form string of
               strings, where each string if of the form "VAR=VALUE"

     The child process inherits all the open handles of the parent, so
     if you had redirected stdout in the parent, it will  be redirected
     in the child too.

     ** BUG ALERT **
     Alcyon C (v4.14 and the earlier version) always returns success (0)
     status, even if there were compilation errors.

Summary: How do you get it?

[]

Does anybody know of a source for the Motorola "MC68000/8/10/12
Programming Pocket Reference Guide" (M68000RG/AD)(A18606)(1984)?

I'm using a borrowed copy. It is a nifty little thing that is ideal
for reference while you're writing in AL. I cannot find it in the local
computer literature outlets. Can you order it from Motorola? Address?
Price? Any alternative sources or books?

This booklet gives, for each mnemonic, a short but precise discription
of the operation, allowed addressing modes, assembler syntax and the
binary machine code (for each addressing mode and attribute). It is about
3.5 by 5 inches and about 120 pages long.

While we're at it: is there, after all, a good PD assembler for the ST?

The GDOS.PRG that Migraph has been sending out with EasyDraw for the
past 7 months is strictly a prerelease version that was debugged enough
to work for EasyDraw. Migraph was apparently working in an IBM -> ST
cross-development environment (the IBM PC version of GDOS/VDI works fine,
I guess...) and they had to have GDOS to release their program. Atari
probably saw EasyDraw as a good product that would help sell quite a
few ST's and worked on getting Migraph a version of GDOS that worked
well enough to get EasyDraw out the door.

Don't get too upset at Neil and the rest of the folks at Atari...
they seem to be taking the time they need to release a really well-debugged
package for us and sometimes that can take a while... all in all, I
would rather wait than get a GDOS that Atari has to continually fix. And
when it's really ready, I bet we'll be seeing some really fantastic
software that takes advantage of all the goodies.

DISCLAIMER: I don't have any affiliation with Atari (obviously.. look at
the ORG line in the header!) but I think lots of us know what it's like to
try to kill every bug in a complicated program as people are screaming at you
to RELEASE it...

sorry to disagree landon but if the program in question is acc_load
that was posted to the net awhile ago, it works just fine allowing
the user to even select which .acc are to be loaded

you want to use the Fdup and Pexec calls, but may i recommend the
Beckemeyer Micro Cshell to you, its not very expensive and will
allow you to do pipes, redirect output etc., but wait there's
more... it comes with a cc.prg that does exactly what you are
looking to do

Are you saying that you would rather program on a 24 x 80 terminal than a 19"-
screen, bit-mapped workstation? (e.g. Sun) If so, either you have never used one,
or are a super-human programmer.

Organization: Theory Center, Cornell University, Ithaca NY
Lines: 50
Summary: Can be used as drive 'C' or 'F'

[]

If you want to use the RAM disk program I've posted as a drive other
than 'D', you have to patch it. This patch is essential if you want to use
a hard disk together with the RAM disk. Here is an old hint:

>From: jdg@elmgate.UUCP (Jeff Gortatowsky)
>   {allegra,seismo}!rochester!kodak!elmgate!jdg
>Subject: Reset survivable RAM disk and Atari HD problem fixed!
>Date: 3 Oct 86
>
>Well after a bit of digging and disassembly my brother (a sharp troop)
>found the correct combination to get the reset surviving RAM disk to play
>as drive F: in a HD system (Atari 20meg).   First, as was mentioned
>before on this news group you need to change the bit set in the 'drivebits'
>variable down in low memory. The BSET #3,d0 needs to be BSET #5,d0 (for
>drive F:). The other patch is applied to the compare instruction in the
>code that is executed when RWABS calls the RAM Disk.   The RAM disk checks
>the device number and if it's not the right number it passes control
>through a JMP instruction to the Hard disk vector the RAM disk saved at
>boot time. The above patches imply that the RAM disk need be executed
>AFTER the hard disk driver is installed, so it may take over and save
>the hard disk vectors.

What I think was meant: Change the bytes at the following
offsets from the beginning of the ".prg" file:

offset	old value(for drive D)	new value (for drive F)
$145 (325)	03	05
$173 (371)	03	05
$181 (385)	03	05
$193 (403)	03	05

The first one is the "BSET #3,D0" in the installation, the other three
are "CMP #3,x(A7)"s in handling calls to disk device drivers.

For drive C instead of F, use the value 02.

To change the default RAM disk size, change the byte at offset
$B3 (179): The value is the size in units of 64K, e.g. 03 for
a default size of 192K, 09 for 576K.

WARNING: These are untested speculations!!!
If somebody tests this (with a hard disk, if possible), please tell us!
Jeff, if you're out there: please confirm &/or post the fix and the
disassembly!

Please forgive the uninitiated and uninformed, but could you explain
a little bit more about what GDOS is exactly? When you mention fonts,
does that mean that this is more like the "real" operating system that
Atari had intended? Or is it an extension of GEM?

By the way, Hawaii distributers have been getting Atari products in, yeah!
Three cheers to Atari!

==========
ATARI CORP. PRESS RELEASE, Sept. 18, 1986

(Sunnyvale, CA) Atari Corporation announced today that it has filed a Registration Statement with the Securities and Exchange Commission for an initial public offering by the Company of 4,500,000 shares of Common Stock (and up to an additional 675,000 shares that may be purchased by the Underwriters from the Company to cover over-allotments) through an Underwriting group to be managed by PaineWebber, Incorporated. The price range is anticipated to be between $11.50 and $13.50 per share, and the offering is scheduled for mid- to late October. A written prospectus with respect to the offering will be available from PaineWebber, Incorporated.

Atari Corporation develops, manufactures, and markets microcomputer systems and software as well as video game systems, designed to offer advanced technology at low prices. The Company's product line consists of the 16/32-bit ST computers, the 8-bit XE computers, and the 2600 and 7800 video game systems, with associated software and accessories.

A registration statement relating to these securities has been filed with the Securities and Exchange Commission but has not yet become effective. These securities may not be sold, nor may offers to buy be accepted prior to the time the registration statement becomes effective. This (communication) shall not constitute an offer to sell or the solicitation of an offer to buy nor shall there be any sale of these securities in any State in which such offer, solicitation or sale would be unlawful prior to registration or qualification under securities laws of any such State.

For more information, please contact Greg Pratt, Chief Financial Officer of Atari Corp. at (408) 745-2349.

YARG!

I am having problems with MT-C SHELL. I suspect it is something i
am doing...but who knows...

Problem one ... how do i get C SHELL to understand the command :
"ls ." (give me a directory listing of the current directory)
in fact all my problems stem from this one. If i have an executable
in my current directory i have to spell it out

    \usr\root\inter\infer animal
to execute infer.prg in directory infer.

YES I know that in login.sh i should have :
          set path = (. \bin \etc)

only when i have this then everything gets lost!!!

That is i try to do an 'ls' and the c shell says :
'ls' not found

If someone could send me their login.sh that works or tell me what I am
doing wrong i would be greatly in their debt.   Thank you,
                         Charles Ditzel
                         ...uw-beaver!ssc-vax!benoni

Summary: HELP!!!

[]

Following this posting you will find a posting of source code
for a program that compresses ST pictures AND codes them into
a text file that can be sent through e-mail. The text file's
length depends on the picture, but for simple pictures (e.g.
an image of a desktop with some icons and an open dialog box)
it is about 4000 to 8000 chars, i.e. 12 to 25% of the bitmap
size in RAM. The combination code/compress algorithm is the
culprit for those ratios.

The program is installed in RAM, and activated later upon an
Alt-Help. Then, instead of printing the screen, it codes it
and saves it on the disk. (I have also written a program that
decodes and decompresses the text file, shows the picture on
the screen, and can also save it uncompressed in DEGAS format.
I am waiting for net.atari16.sources to post it, and the 2
executables.)

To do what it does, the program calls various OS routines (via TRAPs).
But, the program is called from the keyboard interrupt handler,
and it is officially verboten to do OS calls from there!!
I did it anyway, because I didn't know what else to do. And
it seems to work - from the desktop. But when called from
inside micro-C-Shell, the system hangs. Removing all the TRAPs
makes the program docile (but also futile...).

Can some expert out there tell us what to do about it, and/or how
to write files without TRAPs?

- Moshe Braner

```

Apparently-To: rnews@mcvax

Here is a fix for the megamax library, for those who want I/O redirection
from within a shell (command line interpreter). Megamax programs could not be
IOredirected since Megamax' ideas about standard IO are a bit weird.

The problem is caused by the idiotic file desciptor -32000 in the first
three slots of the stdio-stream table '_iob'.

When a character is written to (or read from) these
filedescriptors the MM lib uses probably a low numbered GemDos call
(between 0 and 0x20) to do the IO. But these GemDos calls cause bombs to
appear when the standard GemDos file descriptors 0 or 1 are redirected to
another file by means of the Fdup and Fforce system calls.
So a solution is to overwrite the values of _iob[0]._fd to _iob[2]._fd with
real GemDos file descriptor numbers.
The only drawback is that the lf to crlf mapping by the library is
lost. But this mapping *IS* done when you declare your program as

```
 main ( argc, argv )
 char **argv;
```

Is that documented anywhere ? How does MM-lib work ???

This causes inclusion of the _initargcv module from syslib during linking.
When _initargcv is not included cr to crlf mapping is not done.

The overwriting is done in the routine 'initstdio' which should be called from
'main' before any IO is done.
The 'exitstdio' routine puts the old values back, otherwise the bombs still
appear.

Do not use this trick when your programs are to be IO redirected from the
desktop.

Hope this solves the problem,

    Gert Poletiek

Uucp:
    .... { seismo | philabs } !mcvax!gert@nikhefh.uucp

```
#include <stdio.h>
```

```
/*
 *   Test program
 */

main ()
{
     int  i;

/*
 *   initialize stdio library to use standard GemDos file descriptors 0 and 1.
 */

     initstdio();

     for ( i=0; i<3; i++ )  {
          printf ( "stream %d file descriptor %d\n", i, _iob[i]._fd );
          printf ( "flags = %x\n", _iob[i]._flag );
     }
     fprintf ( stdout, "test\ntest\ntest\n\n" );

/*
 *   reset the stdio library to use the idiot Megamax descriptors again,
 *   otherwise it's possible that the application exits with three bombs.
 */
     exitstdio();
}

initstdio()
{
     _iob[0]._fd = 0;
     _iob[1]._fd = _iob[2]._fd = 1;
}

exitstdio()
{
     _iob[0]._fd = _iob[1]._fd = _iob[2]._fd = -32000;
}

In shuffling versions of code around it seems I inadvertantly deleted
the documentation files for UNITERM. Could someone please mail me
a copy of the documentation? I have been using version 1.5 with
no problems and would also like to add my kudos to Simon Poole for
job well done.

 I have a desk accessory loader in my auto folder that works just
 fine. If you would like a copy of it, send me a note and we'll
 give it a whirl.

Apparently the README file was wrong. We have been looking into the
compatibility issue, and have found some trouble spots -- one big problem is
that programs compiled with OSS Personal Pascal don't work with GDOS. We
have told OSS how to fix this.

> This all disturbs me. Apparently GDOS is already being given away in some
> form with commercial software, but you are telling us that we are going to
> have to pay money for it. Will the GDOS given away with software in the

Why should it disturb you? We are licensing GDOS for use with commercial
packages -- if you get the package, you get GDOS. The current thinking is
to package GDOS separately for consumers who want it.

EasyDraw uses a very early GDOS, under strict directions to their
programmers to use only the functions we explicitely told them were working.
The final version is complete now.

To: "info-atari16" <info-atari16@su-score>
Reply-To: "V5130B::MENTON" <menton@v5130b.decnet>

Is there a limit on the total number of files on an ST disk, either single-sided or double-sided?

While copying over 200 FORTRAN subroutines from an IBM PC/AT to a VAX to the ST (total bytes well below the capacity of a SS disk), the file copy bombed at about 111 files. This same limit was reached (same error message, something about a file not being opened to write ??) when the destination disk was formatted DS. I tried to copy an additional file to the disk, to see if it was a limitation of the XMODEM program. Nope - same error message - the disk would just not take another file, even though it was well below its max capacity.

Any thoughts on why this happened would be appreciated. I don't remember reading about a limit to the number of file names on an ST disk, analogous to the 64-file limit with the 8-bit Atari disk drives.

Would some kind soul give me a serious description on the uCshell and MTCshell packages ? The names are fairly suggestive, but I wonder how functionnaly close to a Unix csh they may be. In particular, are they of any serious use for systems without a hard disk ?
Are we talking freebees here, or are they $old (price ?) ?

Subject: Re: Volume of net traffic
To: info-atari16@score.stanford.edu

I'm not convinced that 'descriptions and mail to requesters' would actually
cut the net traffic. At present (bar accidents) net stuff crosses the Atlantic
once (to Holland, innit?), crosses the Channel once, and so on. A separate
trans-Atlantic posting to each requestor would pretty obviously crank the
transmitted bitcount right up.

Similar arguments, of course, apply to non-international posting. Also,
I think that this net has a higher connectivity than 'pure user mail',
so that solution would leave lots of people out, I spect.

Better, the idea (is it reelly going to happen) of a separate meeting for
the software, so that them as don't want it can more easily miss it out.

Subject: Re: UNITERM V1.5C PART 3 OF 4 (UNITERM.B)
To: info-atari16@score.stanford.edu

Sigh. Someone up there doesn't want me to have UniTerm 1.5c. Our site

finally received parts 1, 2, and 3 of the 16th (19th? it's scrolled off my screen) posting of 1.5c. Assuming that the part 3 I got earlier was correct (got it twice, and they both matched) the new part 3 was savagely truncated =678 lines, missing about 600 if I counted right. Part 2 ('A') was also chopped off short. So, I've now got

  Part 1 Read Me
  Part 2 ('A') 1 bad copy (truncated)
  Part 3 ('B') 2 good copies and one bad (truncated)
  Part 4 ('C') 1 good copy

Of course this all assumes that the Parts were all the same each time. Anyone with UK PSS or JANET access (or US ARPA) willing to trade a part A for one of my spare part B's :-).

  JANET: Smee at AUCC
  ARPA: Smee at AUCC via UCL-CS.ARPA

I copied Rogue over to my hard disk, and it runs fine from there, although it requires the original disk in 'A'... it just accesses it for a couple of seconds. Also, you can only save files to the original disk! But at least the loading time is slashed, especially for those l-o-n-g picture files.

by
John "C". Sucilla

This sucker is pretty long (287 lines). I just downloaded it from Plantz'z machine and thought it might be a good idea to make it available here.
I have no idea if this is for real or not at this time. I hope not!

The Night of the Hackers

. As you are surveying the dark and misty swamp you come across what appears to be a small cave. You light a torch and enter. You have walked several hundred feet when you stumble into a bright blue portal. . . With a sudden burst of light and a loud explosion you are swept into . . . DRAGONFIRE . . . Press Any Key

. You have programmed your personal computer to dial into Dragonfire, a computer bulletin board in Gainesville, Texas. But before you get any information, Dragonfire demands your name, home city and phone number. So, for tonight's tour of the electronic wilderness you become Montana Wildhack of San Francisco.

. Dragonfire, Sherwood Forest (sic), Forbidden Zone, Blottoland, Plovernet, The Vault, Shadowland, PHBI and scores of other computer bulletin boards are hangouts of a new generation of vandals. These precocious teenagers use their electronic skills to play hide-and-seek with computer and telephone security forces. Many computer bulletin boards are perfectly legitimate: they resemble electronic versions of the familiar cork boards in supermarkets and school corridors, listing services and providing information someone out there is bound to find useful. But this is a walk on the wild side, a trip into the world of underground bulletin boards dedicated to encouraging -- and making -- mischief.

. The phone number for these boards are as closely guarded as a psychiatrist's home telephone number. Some numbers are posted on underground boards; others are exchanged over the telephone. A friendly hacker provided Dragonfire's number. Hook up and you see a broad choice of topics offered. For Phone Phreaks -- who delight in stealing service from AT&T and other phone networks . Phreakenstein's Lair is a potpourri of phone numbers, access codes and technical information. For computer hackers -- who dial into other people's computers -- Ranger's Lodge is chock-full of phone numbers and passwords for government, university and corporate

computers. Moving through Dragonfire's offerings, you can only marvel at how conversant these teen-agers are with the technical esoterica of today's electronic age. Obviously they have spent a great deal of time studying computers, though their grammar and spelling indicate they haven't been diligent in other subjects. You are constantly reminded of how young they are.

. "Well it's that time of year again. School is back in session so let's get those high school computer phone numbers rolling in. Time to get straight A's, have perfect attendance (except when you've been up all night hacking school passwords), and messing up you worst teacher's paycheck."

. Forbidden Zone, in Detroit, is offering ammunition for hacker civil war -- tips on crashing the most popular bulletin-board software. There also are plans for building black, red and blue boxes to mimic operator tones and get free phone service. And he re are the details for "the safest and best way to make and use nitroglycerine," compliments of Doctor Hex, who says he got it "from my chemistry teacher."

. Flip through the "pages." You have to wonder if this information is accurate. Can this really be the phone number and password for Taco Bell's computer? Do these kids really have the dial-up numbers for dozens of university computers? The temptation is too much. You sign off and have your computer dial the number for the Yale computer. Bingo -- the words Yale University appear on your screen. You enter the password. A menu appears. You hang up in a sweat. You are now a hacker.

. Punch in another number and your modem zips off the touch tones. Here comes the tedious side of all of this. Bulletin boards are popular. No vacancy in Bates Motel (named for Anthony Perkin's creepy motel in the movie "Psycho"); the line is busy. So are 221 B. Baker Street, PHBI, Shadowland and The Vault, Caesar's Palace rings and connects. This is different breed of board. Caesar's Palace is a combination Phreak board and computer store in Miami. This is the place to learn ways to mess up a department store's anti-shoplifting system, or make free calls on telephones with locks on the dial. Pure capitalism accompanies such anarchy, Caesar's Palace is offering good deals on disc drives, software, computers and all sorts of hardware. Orders are placed through electronic mail messages.

. 'Tele-Trial': Bored by Caesar's Palace, you enter the number for Blottoland, the board operated by one of the nation's most notorious computer phreaks -- King Blotto. This one has been busy all night, but it's now pretty late in Cleveland. The phone rings and you connect. To get past the blank screen, type the secondary password "S-L-I-M-E." King Blotto obliges, listing his rules: he must have your real name, phone number, address, occupation and interests. He will call and disclose the primary password, "if you belong on this board." If admitted, do not reveal the phone number

or the secondary password, lest you face "tele-trial," the King warns as he dismisses you by hanging up. You expected heavy security, but this teenager's security is, as they say, awesome. Computers at the Defense Department and hundreds of businesses let you know when you've reached them. Here you need a password just to find out what system answered the phone. Then King Blotto asks questions -- and hangs up. Professional computer-security experts could learn something from this kid. He knows that ever since the 414 computer hackers were arrested in August 1982, law-enforcement officers have been searching for leads on computer bulletin boards.

. "Do you have any ties to or connections with any law enforcement agency or any agency which would inform such a law enforcement agency of this bulletin board?"

. Such is the welcoming message from Plovernet, a Florida board known for its great hacker/phreak files. There amid a string of valid VISA and MasterCard numbers are dozens of computer phone numbers and passwords. Here you also learn what Blotto means by tele-trial. "As some of you may or may not know, a session of the conference court was held and the Wizard was found guilty of some miscellaneous charges, and sentenced to four months without bulletin boards." If Wizard calls, system operators like King Blotto disconnect him. Paging through bulletin boards is a test of your patience. Each board has different commands. Few are easy to follow, leaving you to hunt and peck your way around. So far you haven't had the nerve to type "C," which summons the system operator for a live, computer-to-computer conversation. The time, however, however has come for you to ask a few questions of the "sysop." You dial a computer in Boston. It answers and you begin working your way throughout the menus. You scan a handful of dial-up numbers, including one for Arpanet, the Defense Department's research computer. Bravely tap C and in seconds the screen blanks and your cursor dances across the screen.

. Hello . . . What kind of computer do you have?

. Contact. The sysop is here. You exchange amenities and get "talking." How much hacking does he do? Not much, too busy. Is he afraid of being busted, having his computer confiscated like the Los Angeles man facing criminal changes because his computer bulletin board contained a stolen telephone-credit-card number? "Hmmmm . . . No," he replies. Finally, he asks the dreaded question: "How old are you?" "How old are YOU," you reply, stalling. "15," he types. Once you confess and he knows you're old enough to be his father, the conversation gets very serious. You fear each new question; he probably thinks you're a cop. But all he wants to know is your choice for president. The chat continues, until he asks, "What time is it there?" Just past midnight, you reply. Expletive. "it's 3:08 here," Sysop types. "I must be going to sleep. I've got school tomorrow." The cursor dances "********** Thank you for Calling." The screen goes blank.

Epilog:

. A few weeks after this reporter submitted this article to Newsweek, he found that his credit had been altered, his drivers' licence revoked, and EVEN HIS Social Security records changed! Just in case you all might like to construe this as a 'Victimless' crime. The next time a computer fouls up your billing on some matter, and COSTS YOU, think about it!

. This the follow-up to the previous article concerning the Newsweek reporter. It spells out SOME of the REAL dangers to ALL of us, due to this type of activity!

The REVENGE of the Hackers

. In the mischievous fraternity of computer hackers, few things are prized more than the veil of secrecy. As NEWSWEEK San Francisco correspondent Richard Sandza found out after writing a story on the electronic underground's (DISPATCHES, Nov. 12, 198\ ability to exact revenge can be unnerving. Also severe.... Sandza's report:

. "Conference!" someone yelled as I put the phone to my ear. Then came a mind-piercing "beep," and suddenly my kitchen seemed full of hyperactive 15-year-olds. "You the guy who wrote the article in NEWSWEEK?" someone shouted from the depths of static, and giggles. "We're going disconnect your phone," one shrieked. "We're going to blow up your house," called another. I hung up.

. Some irate readers write letters to the editor. A few call their lawyers. Hackers, however, use the computer and the telephone, and for more than simple comment. Within days, computer "bulletin boards" around the country were lit up with attacks on NEWSWEEK's "Montana Wildhack" (a name I took from a Kurt Vonnegut character), questioning everything from my manhood to my prose style. "Until we get real good revenge," said one message from Unknown Warrior, "I would like to suggest that everyone with an auto-l modem call Montana Butthack then hang up when he answers." Since then the hackers of America have called my home at least 2000 times. My harshest critics communicate on Dragonfire, a Gainesville, Texas, bulletin board where I am on teletrial, a video-lynching in which a computer user with grievance dials the board and presses charges against the offending party. Other hackers -- including the defendant --post concurrences or rebuttals. Despite the mealtime interruptions, all this was at most a minor nuisance; some was amusing, even fun.

. FRAUD: The fun stopped with a call from a man who identified himself only as Joe. "I'm calling to warn you," he said. When I barked back, he said, "Wait, I'm on your side. Someone has broken into TRW and obtained a list of all your credit-card numbers, your home address, social-security number and wife's name and is posting it on bulletin boards around the country." He named the charge cards in my wallet.

. Credit-card numbers are a very hot commodity among some hackers. To get one from a computer system and post it is the hacker equivalent of making the team. After hearing from Joe I visited the local office of the TRW credit bureau and got a copy of my credit record. Sure enough, it showed a Nov. 13 inquiry by the Lenox (Mass.) Savings Bank, an institution with no reason whatever to ask about me. Clearly some hacker had used Lenox's password to the TRW computers to get to my files (the bank has since changed the password).

. It wasn't long before I found out what was being done with my credit-card numbers, thanks to another friendly hacker who tipped me to Pirate 80, a bulletin board in Charleston, W.Va., where I found this: "I'm sure you guys have heard about Richard Stza or Montana Wildhack. He's the guy who wrote the obscene story about phreaking in NewsWeek Well, my friend did a credit card check on TRW . . . try this number, it' a VISA . . . Please nail this guy bad . . . Captain Quieg.

. Captain Quieg may himself be nailed. He has violated the Credit Card Fraud Act of 1984 signed by President Reagan on Oct. 12. The law provides a $10,000 fine and up to a 15-year prison term for "trafficking" in illegally obtained credit-card account numbers. He "friend" has committed a felony violation of the California computer-crime law. TRW spokeswoman Delia Fernandex said that TRW would "be more than happy to prosecute" both of them.

. TRW has good reason for concern. Its computers contain the credit histories of 120 million people. Last year TRW sold 50 million credit reports on their customers. But these highly confidential personal records are so poorly guarded that computerized teenagers can ransack the files and depart undetected. TRW passwords -- unlike many others -- often print out when entered by TRW's customers. Hackers then look for discarded printouts. A good source: the trash of banks and automobile dealerships, which routinely do credit checks. "Everybody hacks TRW," says Cleveland hacker King Blotto, whose bulletin board has security system the Pentagon would envy. "It's the easiest." For her her part, Fernandez insists that TRW "does everything it can to keep the system secure

. In my case, however, that was not enough. My credit limits would hardly support big-time fraud, but victimization takes many

forms. Another hacker said it was likely that merchandise would be ordered in my name and shipped to me -- just to harass me. I used to use credit-card numbers against someone I didn't like," the hacker said. "I'd call Sears and have a dozen toilets shipped to his house."

. Meanwhile, back on Dragonfire, my teletrial was going strong. The charges, as pressed my Unknown Warrior, include "endangering all phreaks and hacks." The judge in this case is a hacker with the apt name of Ax Murderer. Possible sentences range from exile from the entire planet" to "kill the dude." King Blotto has taken up my defense, using hacker power to make his first pleading: he dialed up Dragonfire, broke into its operating system and "crashed" the bulletin board, destroying all of its messages naming me. The board is back up now, with a retrial in full swing. But then, exile from the electronic underground looks better all the time.

Dave I.

I'm not surprised. If *I* ever get my hands on one of these little theives, I'll show him or her how a professional can scramble their silicon...

Seriously, I don't know how anyone expected something different. We can teach kids all the tech skills necessary to do these things, but it's just not considered part of either the formal curriculum, or a parent's duty, to teach a sense of ethics about use of such skills. I once let loose on a bunch of students at U of W who were on the system staff; they considered it perfectly OK to read anyone's electronic mail that passed through their machine, or between students and professors. Not only that, but if you annoyed one of them, you might find your files munged or missing. By the time I got through, I'm sure that they got my message. Don't believe for a moment that they'd do anything about it, but they knew that when they got out into the 'real world', if they ever did something like that and I caught them, they'd be fired--or worse.

Oh, well...this is just one of my sore points. These twits are going to ruin it for all the rest of us, unless we police them ourselves...

meg

We get a few phreakers or hackers on M-Net now and then, at least they claim to be, mostly we drive 'em out by means of some 'practical jokes'

we engineer, that and a combination of the fact that Mike states every where and anywhere that if anyone comes investigating, all his files and stuff are open and for the record. That usually keeps it at a minimum, and they are never around long enough to cause any trouble on the board, nor do anything illegal.

Was interesting tho, a conversation I had with someone who professed to be a hacker, no longer on M-Net, and his absolute conviction that what he was doing was perfectly alright and he honestly believed no one had a right to complain. I was completely dumbfounded, myself.

rob

Anyone have any ideas of how we can rid the computer world of these types? It's always the bad who receive publicity...

Arthur F.

I hate to say it, but business should have adopted a different equivalent of the ASCII code for transfering data

jjw

Easiest way to rid the world of these is to have intelligent people in charge of setting up security in the first place, followed by more intelligent people using it.
 I had my share of this s**t at Harper College, where a bunch of local phreaks thought they could run the system out from under the school. I did them one better - joined the school and ran it as secure as I could make it (within the limits that the school itself imposed).
 Some general ideas - y'all remember a few years ago the kid that broke into DePauls system? I knew him, and the other guy who helped was my friend's cousin (both sorta twits). It helped that DePaul kept last years password list as a readable ascii file, open to public inspection. Seems they used 3 character passwords. Also, the first letter was between A and M. Took about 20 minutes to break through. When they changed it, the new password followed the same format. The program that allegedly did so much damage had been around for several months. All the authorities denied that it could possibly crash the system, and refused to listen to me when I told them. Eventually, HP came up with a fix that took care of it, but DePaul somehow didn't think it needed that fix.
 I'd kind of like to make the sys administrators liable for damages on any system that gets broken into. It would encourage them to take much better care in designing the security.
 Oh, also, on my home BBS system (not yet up, but getting there slowly), I have a sure way to prevent anybody from getting through. Even supposing that they can crash the program, the modem's hooked up to the serial printer port. I do *all* my own i/o, and if it crashes, they're not a console, they're a printer and the system ignores them. Also, I am *not* going to allow so-called 'sysop' stuff to be done from within the system. To do these functions, you'll have to be physically in my apt, at my terminal, running programs outside of the bbs system. The worst I can come up with would be to bring each user down, but even that won't let anybody do anything un-cool.

kji

I like the idea of the i/o through the serial printer stuff. I could
throw up a board in not time if I only had the smart modem. Have all
the programs setup with tons of pd stuff, but no $ for the modem.

jcs

Here's an idea for twit control: Uzi's & Mac 10's are rarely argued with.

bhv

If kids can get into the credit bureaus, imagine what the professionals
can do. It seems to me that the credit bureaus are the weak link in the
chain, and it would be better to work on increasing their security than
to try and police every kid in existence.

greg

I have little worry of a serial port of any kind being turned into a tty
controlling the system since {there's no way to control the mouse via
that port.. and even if they could, they couldn't see what they were doing
anyway..

Problem solved...

rlk

I don't think the credit agencies themselves are bad, its the clients
who don't maintain security of their passwords. I've seen several
places where access passwords were taped to the wall over the
terminal, and the terminals were in public access areas so that
everyone 'knew' the shop was computerized. One place must have
had a nearsighted operator, 'cause the password had been written
using a magic marker. You could read it from the lobby.

pgy

There is also the other extreme of security. I'm currently working on
a team programming project for which we have a librarian who maintains
among other things, the include files for the system. I came in today
and reran the make file for my current sub project. I was immediately
informed that cc could not find the include files. I thought that
perhaps the files had been reorganised (this is something I've been
told to expect soon). But upon further investigation, I found that
read permission for the world had been removed from the include
directory. In order to access these files I had to newgrp to the
special group which only the librarian defaults to, and then re-run
the make. It was a small annoyance, but it was an an
annoyance. These files are most decidedly NOT secret -- there was no good
reason to take read permissions off of that directory. Especially in a
development environment, security should be only as tight as necessary.

jcs

There is a new guy in our department who was doing the same thing.
He had post-its with logins & passwords for all the Indian Hill machines
we use hanging all around his terminal. He even had his login/password
for our machine embedded in his function keys. It took about 10 minutes
to convince him that we WOULD use his login to wreak havoc on his files
if he didnt get rid of the stuff. He cleaned up his act in a hurry!
LMHY:
Sounds like you could use the Change Management System (CMS) available
from Bell Labs. It would make everybody's life easier there.
CMS=Change Management System.
Let's say you have a product that consists of N directories
with a couple hundred source files involved (ours consists of a few thousand
files). You have X number of developers working full time on the product
and the files are in a constant state of flux. Under CMS, only one developer
can modify a file(s) at a time. All other developers are denied access to
the file(s) until he is done with it. There are typically three "nodes"
available to the CMS user. 1) The "Official" node - where the last release
was generated from. 2) The "Approved" node - where files are kept after
they have been approved by the test team and before an integration has
been performed. Integration moves the files from approved to official.
3) The "Local" node - where changes are made and proved in by the developer.
Here is a simplified scenario of a change:
 Programmer jcs needs to change x.c for some reason. He generates an MR
 (modification request). Once the MR is approved by commitee (if there is one)
 and assigned he gets the latest version of the file from the official node.
 Thats right, SCCS is involved here. He makes the required changes to the file
 and builds the product in his local node. The build command utilizes
 a viewpath which tells build where to look for the files it needs to create
 the product. If the viewpath looked like this -

  VPATH=/prod/ofc:/prod/appr:/prod/localnode
 build would first search /prod/ofc for the files it needs then look in
 /prod/appr for any missing files then /prod/localnode. If a file in
 /prod/localnode is newer than a matching file in the other nodes it is
 used instead. Now that the product is built, the developer checks it out
 on whatever hardware it was built for and once he's satisified with it
 he passes it on to the test team. If the test team kisses the change,
 the change is moved into the approved node and eventually into the
 official node.

For large projects, CMS can't be beat. It's a logical way to synchronize
changes and prevent a lot of unnecessary confusion.
For small projects it's probably a lot easier to rap the bozo next door
in the head for screwing around with your struct than it is to justify CMS.
CMS is available from Bell Labs.

Back to original topic for...

I find it hard to get worked up if someone looks through my files. I think

damaging (deleting/changing/encrypting/etc) files is a different matter.
I dunno, but I certainly think your 'anti-hacker/phreak' stance is a bit
more extreme then warranted.

There was a short note in this month's BYTE magazine mentioning that Atari had
released a 2 and 4 megabyte version of the ST in europe somewhere. Does anyone
out there (ATARI??) have some more information on this? The new machine was
said to have a bit-blit chip. I would be very interested to know if there
are any new graphics modes with more colors/higher resolutions.

Just for the record (I used to work for Migraph):

> The GDOS.PRG that Migraph has been sending ...
> is strictly a prerelease version ...

More accurately, it is strictly the only version that has been available to an ST developer up to this point. Apparently it was a direct port by DRI from the PC ("We Port Bugs"). Migraph requested it and DRI gave the go-ahead to release it (and Output) with Easy-Draw.

> Migraph was apparently working in an IBM -> ST
> cross-development environment (the IBM PC version of GDOS/VDI works fine,
> I guess...) ...

No, on genuine first-generation 520's. Trying to do it from the PC would have been even more of a nightmare. The PC version of GDOS works. Just. Easy-Draw was the first program designed to use ALL of the features of GEM (working or not!).

> Atari ...
> worked on getting Migraph a version of GDOS that worked
> well enough to get EasyDraw out the door.

Atari did all they could to help, under the circumstances (some of this stuff was apparently never explicitly licensed to Atari by DRI). They also helped Migraph *beg* DRI for the changes we all may receive shortly.

> Don't get too upset at Neil and the rest of the folks at Atari... I
> would rather wait than get a GDOS that Atari has to continually fix.

Amen! I was the lucky person who got find some of the BUGS in that version and report them to Atari and DRI. If all goes well, the new version should include mulitple font loading, hard disk support, and none of those silly boot-drive defaults (like OUTPUT.RSC and font files).

Incidentally, Migraph did not "give away" GDOS with Easy-Draw. Each developer should make their own agreement with Atari and DRI, not take the stuff off the Easy-Draw disk.

Finally, I suspect (and refer this to Neil for confirmation) that the GDOS itself will not be the item for sale, but the *very expensive* fonts and device drivers which it uses.

To Whom It May Inspire to Help-

     Some years back I read an article (possibly in COMPUTE!) regarding the use of a servo via the joystick ports. The interesting part of the article was the explanation, and subsequent programs, allowing the joystick port to be accessed for *output* from BASIC. If anyone has this article or relevant ones, I would be very appreciative. The end goal is to run a UART-based switching system for the Atari 800.

Maybe sometime in the future, but not now. This really ticked me off when I got my 1040. The decision to release them without composite or RF output seems to have been made at the last minute, as the manual shows you where to hook it up, and there's a different texture in the plastic at the rear of the case where the RF output ought to be. Plus they give Neochrome away with the computer so you can watch it not work on a mono screen. If someone knows a way to get composite output I'd like to know how.

In article <758@zen.BERKELEY.EDU> c9c-bg@buddy.Berkeley.EDU (James A. Landay) writes:
>Has anyone had the problem of their ST upon booting (TOS in ROM) saying
>that every disk was empty. (i.e. 0K in 0 folders). Mine is doing this.
>I have a single sided drive.
>Help!!!
>
>
>James Landay
>c9c-bg@buddy.berkeley.edu

I had a lot of trouble with this when I had my TOS on disk . I had 2 versions .. A UK version and the usual US version . Some files ,in particular folders , were deemed to be empty by the US version if they were created in the UK version . Top level directories were ok but any sub-dir was empty according to the US one. UK reading US created disks had no problems ....!
Dunno if this is any help but here goes anyway .

Got this in the mail and thought it would be of general interest.
In case you missed it, this is a response to my article on the 3.5"
DS Epson drive upgrade for the SF354. There is a problem with the
non-boot drive (B:) not being recognized by the system unless a disk
(even a blank one) is in it.

OK, any ideas? How about just shorting out the disk in
position switch? :-)

The patch works as advertised; thanks Moshe!

BTW, I changed the byte to "0C" for Drive "M" since
I already have a hard disk partition called "F".

I *think* I have finally managed to collect all the bits. I got the
README and parts b and a from a 'second-source'. (I already had c.)
The part b I just got matches the part b I'd already had, so I'm hoping that
I've now got the full set. However, I haven't ported it onto my ST and
uudecoded/de-arced it yet. If I can find a JANET path from UK.AC.AUCC to
your machine, I'll try to mail it to you, unless I hear rather quicly that
you'd as soon not be the guinea-pig.

Anyone else in the UK who is accesible to JANET mail, and in a similar situation,
send me mail ***AT MY PRIMARY MACHINE*** (poor connectivity). E-mail address
for there is:

   Smee at UK.AC.AUCC

(In theory, I can also get at ARPA via UCL-CS gateway, and at BITNET via RL.EARN
gateway, but I haven't been terribly successful at those. Still, if anyone
wants to try to establish a mail path between me (at AUCC) and somewhere on
those nets, I'll be happy to give that a try as well...)

May I suggest that the real problem is the lousy way that the macro

is defined! Look at the BSD4.2 macro to see how things should be done.
Library macros should be pretty well equivalent to library functions,
with no side effects.

I find that if I boot up my machine (520, TOS in ROM) with a joystick
attached to port 2 (the non-mouse port) the machine comes up with the
keyboard effectively disabled, and I have to unplug it and reboot. If
I plug it in after the machine has booted, everything is happy.

Admittedly, it's an '8-bit' Atari joystick model, but still...

Anyone else seen this? Have any clues? Helpful hints and suggestions?

~~~~~~~~~~~~~~~~\ lineater, \~~~~~~~~~~~~~~~~~~~~

if you're going to look for ways to cheat, you might try looking in
the executable for the rogue's name (i.e. what you type in for the
name) that allows you to create anything, scrolls, weapons etc. It's
literally right there in front of you in the code. nuff said..

but i agree with you it takes all of the fun out of the game

on another subject; is anyone out there playing Phantasie I ? (if you
like rogue, you will fall in love with this game) i have gotten all
of the rings and runes and found the black knight's dungeon but
i can't get him, what am i doing wrong ?????

sorry to disagree landon but if the program in question is acc_load
that was posted to the net awhile ago, it works just fine allowing
the user to even select which .acc are to be loaded

Subject: TRAPs from an interrupt handler and micro C Shell
To: info-atari16@score.stanford.edu

[]

Following this posting you will find a posting of source code
for a program that compresses ST pictures AND codes them into
a text file that can be sent through e-mail. The text file's
length depends on the picture, but for simple pictures (e.g.
an image of a desktop with some icons and an open dialog box)
it is about 4000 to 8000 chars, i.e. 12 to 25% of the bitmap
size in RAM. The combination code/compress algorithm is the
culprit for those ratios.

The program is installed in RAM, and activated later upon an
Alt-Help. Then, instead of printing the screen, it codes it
and saves it on the disk. (I have also written a program that
decodes and decompresses the text file, shows the picture on
the screen, and can also save it uncompressed in DEGAS format.
I am waiting for net.atari16.sources to post it, and the 2
executables.)

To do what it does, the program calls various OS routines (via TRAPs).
But, the program is called from the keyboard interrupt handler,
and it is officially verboten to do OS calls from there!!
I did it anyway, because I didn't know what else to do. And
it seems to work - from the desktop. But when called from
inside micro-C-Shell, the system hangs. Removing all the TRAPs
makes the program docile (but also futile...).

Can some expert out there tell us what to do about it, and/or how
to write files without TRAPs?

- Moshe Braner

Subject: Patches for the RAM disk program
To: info-atari16@score.stanford.edu

[]

If you want to use the RAM disk program I've posted as a drive other
than 'D', you have to patch it. This patch is essential if you want to use
a hard disk together with the RAM disk. Here is an old hint:

>From: jdg@elmgate.UUCP (Jeff Gortatowsky)
>   {allegra,seismo}!rochester!kodak!elmgate!jdg
>Subject: Reset survivable RAM disk and Atari HD problem fixed!
>Date: 3 Oct 86
>
>Well after a bit of digging and disassembly my brother (a sharp troop)
>found the correct combination to get the reset surviving RAM disk to play
>as drive F: in a HD system (Atari 20meg).   First, as was mentioned
>before on this news group you need to change the bit set in the 'drivebits'
>variable down in low memory. The BSET #3,d0 needs to be BSET #5,d0 (for
>drive F:). The other patch is applied to the compare instruction in the
>code that is executed when RWABS calls the RAM Disk.   The RAM disk checks
>the device number and if it's not the right number it passes control
>through a JMP instruction to the Hard disk vector the RAM disk saved at
>boot time. The above patches imply that the RAM disk need be executed
>AFTER the hard disk driver is installed, so it may take over and save
>the hard disk vectors.

What I think was meant: Change the bytes at the following
offsets from the beginning of the ".prg" file:

offset	old value(for drive D)	new value (for drive F)
$145 (325)	03	05
$173 (371)	03	05
$181 (385)	03	05
$193 (403)	03	05

The first one is the "BSET #3,D0" in the installation, the other three
are "CMP #3,x(A7)"s in handling calls to disk device drivers.

For drive C instead of F, use the value 02.

To change the default RAM disk size, change the byte at offset
$B3 (179): The value is the size in units of 64K, e.g. 03 for
a default size of 192K, 09 for 576K.

WARNING: These are untested speculations!!!
If somebody tests this (with a hard disk, if possible), please tell us!
Jeff, if you're out there: please confirm &/or post the fix and the
disassembly!

Subject: problems with MultiTasking C shell
To: info-atari16@score.stanford.edu

YARG!

I am having problems with MT-C SHELL. I suspect it is something i
am doing...but who knows...

Problem one ... how do i get C SHELL to understand the command :
"ls ." (give me a directory listing of the current directory)
in fact all my problems stem from this one. If i have an executable
in my current directory i have to spell it out

    \usr\root\inter\infer animal
to execute infer.prg in directory infer.

YES I know that in login.sh i should have :
          set path = (. \bin \etc)

only when i have this then everything gets lost!!!

That is i try to do an 'ls' and the c shell says :
'ls' not found

If someone could send me their login.sh that works or tell me what I am

doing wrong i would be greatly in their debt. Thank you,
                        Charles Ditzel

   Well, I've tried running it from a RAMdisk copy, and it wouldn't run, even *with* the original diskette in drive A. Also, although I haven't actually saved a game on an alternate diskette, I've subsequently copied saved game files to another diskette, and have loaded them from that diskette (in drive B). Works great!
   Lastly, after reading (Ian Chadwick's?) column in the most recent Analog, I took a look at the executatble file. It was entertaining finding phrases like "Software Pirate", "Copy Protection Mafia", and "Scum of the Earth." (Ian, by the way, changed the "die roll" figures in the executable, thereby making his character much better, allowing him to get the Amulet. Kinda defeats the purpose of the game, doesn't it?)

Subject: Printer Problem
To: Info-Atari16@SU-SCORE.ARPA

Hello,

    I've got a problem with a printer here, and I was wondering if someone here can help me out. We are trying to connect a Okidata ML-192 printer

to the ST. Problem is that the printer is randomly repeating a character
that is sent to it. Sooooo, we tried changing the printer cables, no luck.
Changing the ST to another ST, no luck. Changing the printer for another
printer, no luck. Tried the printer and STs with other printers and computers
and everything was fine, it is ONLY when we have an Okidata ML-192 printer
connected to the ST. Contacted OKIDATA, they are not aware of the problem
and insist that it is the Atari's fault. Contancted Atari, they were of no
help either. Does anybody out there have a Okidata ML-192 printer connected
to an Atari? Any help will be greatly appreciated. Is this something like
the ole SONY monitor that was advertised to work with the st, but didn't?

     The version if Gdos that we recently received from Atari does indeed
allow multiple font loading (from any directory), etc. One thing that i was
rather surprised to find was that Ataris version of Gdos does not support
NDC coordinates (Landon/Neil can you shed some light on why ??). In any case
i feel NDC coordinates are quite useless, and what would be more usable
are user defined world coordinates (only metafiles support them), that
Gdos converts to RC in the appropriate way so that drawing primitive still
come out right (at least on the screen??). Also NDC coordinates are quite
useless in Gem as AES does'nt use them anyway. Can someone from DRI/Atari
explain why AES was designed in this way (rather why Gem was half done??),
or were NDC coordinates added into Vdi as an after thought??

Keywords: *** IMPORTANT WARNING ***

Maybe someone's said it before, though I've been watching a lot longer
than i've been talking and haven't seen it. I am using 'over-formatted'
disks for bulk storage of some things. However there is one short-coming
which people should be aware of. Some programs think they know what a
disk looks like and will not work on, or with, nonstandard disks.

    ******* IN PARTICULAR *******

The desktop 'whole disk copy' (move disk icon A over disk icon B) will
NOT properly copy a whole 410K disk onto another 410K disk. It
looks like it is working, but in fact only 9 sectors per track get
copied over. The 10th on the target disk is left containing the trash
pattern put in by the formatter. (This is definitely true with the
version of ROM TOS which I've got. If other people don't have this
problem, you're lucky. At least check first, before counting on this.)

I suspect that the 'whole disk copy' also only knows about 80 tracks per disk and that it will therefore do the wrong thing with 82 track 9sector disks, but I haven't checked that.

File-by-file copies appear to work fine -- though I confess I now do a compare between source and target files before trusting the result as backup.

How did you get GDOS from Atari? When I called the other day, they told me that either I had to pay the $500 licensing fee per product per year, or I could send my software that didn't use GDOS to them "for testing". I was told that if I wanted to do that testing myself, I should buy some commercial software that has GDOS on the disk and use that copy.

Can anyone shed some light on this?

   Huh? Are you saying that green cheese falls from the sky in .6 micron
spheroids? Can you say confused? How about non sequitur?
.....

Just to keep this Atari-related, a question:

   Why are things like ST Rogue usually advertised using grungy IBM screen
photos? The ST version is wonderfully detailed, and is almost worth the
price just to admire the artwork. The IBM version uses those silly
IBM screen "graphics" characters, while the ST has individual mini-icons
for the rogue, for each type of monster (they even all have shadows!), and
for each type of item or trap, as well as good representations of passageways
(with cobblestones) and rooms (rather than the IBM/mainframe style of dots
and dashes). Even the Atari Explorer (BTW, nice pic, Neil...) had an IBM-style
photo along with the ST Rogue article. Why give people a poor impression of
a nice machine and superior version of the software?

Subject: RE: Limit on number of files on Atari disks?

Yes, the limit on the number of files in the ROOT directory is 112 (just like
on a IBM-PC or so), but you should be able to but as many as you want in to
a Subdirectory (this is naturally limited by the size of the FAT, but you
wont have that many files:-)).......the nasty thing is that it bombs on you...
BTW it seems as if the file_selector can only handle 112 entrys as well....
which is very annoying with the large directorys you have to have with a hard
disk (when is this going to be fixed?). More reading on the structure of
MS-DOS or TOS Disks -> Norton's Inside the IBM PC.

Subject: Re: Redirection of stdout and chaining

To: INFO-ATARI16@SU-SCORE.ARPA

 Stdout can be redirected using "freopen()". The documentation for the Alcyon compiler is very terse about this function, but a good description is given in Harbison & Steele (p. 192 I believe). The freopen() function is normally used to reassign the stream handles for stdin, stdout or stderr to another stream (generally a file). Note that freopen() will return a NULL pointer on failure or the stream handle if successful. Also, freopen() will *always* close the input stream, even on failure, so be careful.

 A generalized stream redirection function can be written as follows (I haven't had a chance to test this, since my machine is down):

```
FILE *redirect(infile,outfile,mode)
FILE *infile;
char *outfile, mode;
{
   FILE *stream, *freopen();

   if ((stream = freopen(outfile,mode,infile)) == NULL)
   {
      fprintf(stderr,"Could not redirect to file %s\n",outfile);
      return(NULL);
   }
   else
      return(stream);
}   /* end of redirect() */
```

a use of this function to redirect stdout would be:

```
main()
{
   FILE *redirect(), *str_ptr;
           .
           .
    /* some stuff */

   if ((str_ptr = redirect(stdout,"errors.txt","w")) == NULL)
           .
           .
   /* some more stuff */
}
```

I wasn't able to find out any information about whether the Alcyon compiler sets any error flags. It must do so internally, but I don't know whether those would be available to an external program. If an error flag is set in the CPU, then things would be set. Does anyone out there have any info on the compiler operation?

Subject: Pascal programming
To: Atari Mailing List <info-atari16@score.stanford.edu>

Does anybody out there have experience using Personal Pascal? I would
like to try using sprites with it but need a way to define them. As far
as I can tell, Pascal doesn't have any facility for including data with
the program--- It would be nice to have a segment of the program devoted
just to the hex data for some sprite without using a separate assignment
statement for every byte. This problem extends to other areas as well,
such as perhaps storing instructions for a program without having a bunch
of WRITELN statements. If I haven't made myself clear yet, what I want
is the equivalent of a DC.W statement for Pascal.
  Thanks in advance for comments.

Subject: signing up

Dear Atari16,

This is my second attempt at getting on a mailing list on arpanet and so I'm
not too sure how to go about it . Maybe this time I'll be more sucessfull.
I'm not too sure how these lists work but I'm willing to try it.

I own an atari 520st which I've had since july '85. It's my second one
actually (the first one, may it rest in peace, was replaced by atari
last month for $95.00).

If there are programs that I can download I'm hoping that I can find out how

to do this. I am also interested in networking ST's.

If perhaps this letter is ending up in the wrong place please drop me a line and tell me what's happening. I wonder if there are any special things which have to be done since I'm coming from Bitnet.

Maybe sometime in the future, but not now. This really ticked me off when I got my 1040. The decision to release them without composite or RF output seems to have been made at the last minute, as the manual shows you where to hook it up, and there's a different texture in the plastic at the rear of the case where the RF output ought to be. Plus they give Neochrome away with the computer so you can watch it not work on a mono screen. If someone knows a way to get composite output I'd like to know how.

Subject: New ST models?
To: info-atari16@score.stanford.edu

There was a short note in this month's BYTE magazine mentioning that Atari had released a 2 and 4 megabyte version of the ST in europe somewhere. Does anyone out there (ATARI??) have some more information on this? The new machine was said to have a bit-blit chip. I would be very interested to know if there are any new graphics modes with more colors/higher resolutions.

> that comes with PaintPro claimed that it would work with GDOS installed.

Apparently the README file was wrong. We have been looking into the compatibility issue, and have found some trouble spots -- one big problem is that programs compiled with OSS Personal Pascal don't work with GDOS. We have told OSS how to fix this.

> This all disturbs me. Apparently GDOS is already being given away in some
> form with commercial software, but you are telling us that we are going to
> have to pay money for it. Will the GDOS given away with software in the
> future be the same thing that is going to be sold for money separately?

Why should it disturb you? We are licensing GDOS for use with commercial packages -- if you get the package, you get GDOS. The current thinking is to package GDOS separately for consumers who want it.

EasyDraw uses a very early GDOS, under strict directions to their programmers to use only the functions we explicitely told them were working. The final version is complete now.

Just for the record (I used to work for Migraph):

> The GDOS.PRG that Migraph has been sending ...
> is strictly a prerelease version ...

More accurately, it is strictly the only version that has been available to an ST developer up to this point. Apparently it was a direct port by DRI from the PC ("We Port Bugs"). Migraph requested it and DRI gave the go-ahead to release it (and Output) with Easy-Draw.

> Migraph was apparently working in an IBM -> ST
> cross-development environment (the IBM PC version of GDOS/VDI works fine,
> I guess...) ...

No, on genuine first-generation 520's. Trying to do it from the PC would have been even more of a nightmare. The PC version of GDOS works. Just. Easy-Draw was the first program designed to use ALL of the features of GEM (working or not!).

> Atari ...
> worked on getting Migraph a version of GDOS that worked
> well enough to get EasyDraw out the door.

Atari did all they could to help, under the circumstances (some of this stuff was apparently never explicitly licensed to Atari by DRI). They also helped Migraph *beg* DRI for the changes we all may receive shortly.

> Don't get too upset at Neil and the rest of the folks at Atari... I
> would rather wait than get a GDOS that Atari has to continually fix.

Amen! I was the lucky person who got find some of the BUGS in that version and report them to Atari and DRI. If all goes well, the new version should include mulitple font loading, hard disk support, and none of those silly boot-drive defaults (like OUTPUT.RSC and font files).

Incidentally, Migraph did not "give away" GDOS with Easy-Draw. Each developer should make their own agreement with Atari and DRI, not take the stuff off the Easy-Draw disk.

Finally, I suspect (and refer this to Neil for confirmation) that the GDOS itself will not be the item for sale, but the *very expensive* fonts and device drivers which it uses.

[]

     How does one replace a string with a null-string using

uEmacs 3.7i?

I do the following (which works but seems very indirect):

{ESC}R<string>{ESC}{CTRL-Q}{SP}{BSP}{ESC}

Is there a more direct way?

-anees

ps. Thanks to James and the other netters who have posted some
very high quality stuff.

As far as I know, it's a common problem with the Atari joysticks (only the _real_ Atari joysticks?). An ST-dealer I know frequently complains about this, although I may add I never experienced the 'hangup' myself. My Atari 1040 ST (with ROM's [even specia
l U7 ROM with much faster disk-access] never 'hangs' under normal circumstances - joystick or no joystick connected).

Reply-To: csc@watmath.UUCP (Tracy Tims)
Organization: U of Waterloo, Ontario
Lines: 48
Summary:

I (with some others) am in the process of building a printable character archiver, called "earthpig" (it's an aarchiver, :-)). The following is an example of the compression its printable character encoding algorithm gets.

The "test" file is /bin/vi. I have shown the compression ratios for the various interesting files. A file ending in "pig" is an earthpig encoded file. A file ending in "uue" is a uuencoded file. A file ending in 'Z' is a "compress"ed file.

```
test     131338
test.Z         70103   (0.533 of test)
test.pig 143087   (1.090 of test)
test.uue 180979   (1.378 of test)
test.pig.Z     73175
test.uue.Z     94691
test.Z.pig     96698   (0.736 of test)
test.Z.uue     96611   (0.735 of test)
```

For compressed data, it does about as well as uuencode. For uncompressed data it's quite a lot better. Small binaries (under 20K) shrink slightly. C programs and text files shrink slightly or stay about the same.

Earthpig uses only the characters

```
+-abcdefghijklmnopqrstuvwxyzABCDEFGHIJKLMNOPQRSTUVWXYZ
@.,;:=?*"'/!()_%&
```

This character set should make it through almost anything unchanged. The algorithm only uses table lookup: no bit masking or shifting.

When we finish the archiver we will post various versions of it to the net.

What it does:

- can generate correction requests from errors
- can generate patches from correction requests
- CRC checking on two levels
- supports os independent hierchical file names
- high immunity to format changes and noise characters (space/control)
- close to 1:1 encoding on uncompressed data

The basic goal of earthpig is to provide a single tool that will allow the transfer of arbitrary data and software around the network while providing a very high level of confidence that the data arrived correctly.

I have heard rumours about these products but I have not actually seen
them. Has anybody? What are they like? In particular, what is their
programming interface to the graphics environment and window system like?

Is it just a bunch of calls to do the bindings, or do they support higher
level things?

Reply by mail, please.

To save some people some trouble:

chkdsk (posted some time ago) only seems to work on a hard disk
(default drive c), not a floppy. Has anyone modified it to work on a
floppy?

If it does, will it (and other programs) work with the formater program
recently posted, i.e. on a floppy created by formater with either 9 or
10 sectors per track and either 80 or 82 tracks per disk. Incidentally,

I would be interested to know how the option for formatting disks for
fast reading works.

Formater is incompatible with the mousetrap program posted with the
second issue of STart, because both use the right hand mouse button.
Thus, if you want to use formater, don't put mousetrap in the auto
folder.

ACC_LOAD showed up here today. Looks like just another case of order
shuffling, so that US comments about it came before it did.

*** REPLACE THIS LINE WITH YOUR MESSAGE ***

What follows is a simple program that dumps the format of an executable,
and displays the symbol table (if any). Both the standard and Mark Williams
symbol tables can be displayed. The dumper checks the integrity of various
aspects of the format, and can thus be used to see if a program has been
properly transmitted over the net.

I hope someone finds it useful. I use a modified version of the routine
to load and relocate my own .PRG's, my own Pexec() if you will.

The source compiles under Alcyon (v4.14) and Mark Williams, I have not
tried it under Megamax, but there shouldn't be any major problem.
(Of course, Megamax does not spit out ANY form of symbol table, since
 everything is PC relative)

Another "bug" I have found in uEmacs, probably more of a feature, is that,
unlike the older uEmacs, it uses <NL> at the end of a line, as opposed to a
<NL> and a <CR>. Try writing any sort of file, or modifying anything with
uEmacs 3.7, and SHOWing it from the Desktop. Also, if your Desktop.Inf file
doesn't end with a sequence of NL and CR on each line, the Desktop will do
strange things. After the first task (SHOW) or application, the mouse button
speed will suddenly slow down. Has anyone else had this happen?

No quote worth saying.

No word will be forthcoming on hardware products until they pass FCC.

The blit chip (which will be available as a ~$120 upgrade to older ST's)
will not add new resolutions -- it is not an upgrade to the video shifter,
it is a chip chich performs bit block memory transfers.

>on posting binaries and source code here until this issue is cleared...
>
>- Moshe Braner
>

Huh??? I did't know that it was that hard to contact me...

Anyway, I'm in the middle of changing jobs, but I WILL be moderating comp.sources.atari soon as I get News up at my new employer. That will be by Thanksgiving.

In the meantime, send your sources, binaries (and your kids if you can...) to:

UUCP:

```
     allegra       \
     amd       \
     decvax!bbncca   \
     harvard          \
     cca          + ! ima ! pbear ! peterb
     cbosgd           /
     wjh12           /
     ihnp4          /
     yale     /
```

This is my machine at home, so I'll save everything over the next few weeks and then when the group is formed, I'll start posting.

Please include a well known return path in the message so I can get a reply to you. I will consider all entries and send back a message either accepting the stuff, or a reject message with a suggestion for changes. Please keep the messages below 65K since my mail connection limits messages to that length. I don't want to overload the network.

I'm assuming that I will be flooded with a ton of sources, so PLEASE: if you have to break up a submission, put section numbers on the pieces. I can accept compressed and uuencoded binaries, but the compression can only be 12 bit (compress -b12). I'm soliciting ideas for having a compresssion scheme that is usable and doesn't need a big VAX to run. Please mail your ideas to me.

In order to keed the netload down some, I'll be posting only about 65K per day, so there will be a backlog.

I'll also be soliciting ideas and kind people to help with a tape archive service, so if you have any ideas, please drop me a line.

Peter Barada

This newsgroup is being renamed from net.micro.atari16 to comp.sys.atari.st.
This renaming will gradually take place over the next few weeks.
More and more messages posted to this newsgroup will be aliased
into the new newsgroup as they pass through the net, and people
will begin to post to the new group. After a few weeks, the
old name will be removed.

This note is to inform you of the renaming so you can begin to
read the new group as well as the old group.

Autocopy compiles but it doesn't work as expected. It says h/filename
'not able to write'. Does anyone know how to fix this problem?
Comments are appreciated.

To: info-atari16@score.stanford.edu

Got this in the mail and thought it would be of general interest.
In case you missed it, this is a response to my article on the 3.5"
DS Epson drive upgrade for the SF354. There is a problem with the
non-boot drive (B:) not being recognized by the system unless a disk
(even a blank one) is in it.

OK, any ideas? How about just shorting out the disk in
position switch? :-)

The patch works as advertised; thanks Moshe!

BTW, I changed the byte to "0C" for Drive "M" since
I already have a hard disk partition called "F".

In article <191@slovax.UUCP> michael@slovax.UUCP (Michael Longe) writes:
>Amen! I was the lucky person who got find some of the BUGS in that
>version and report them to Atari and DRI. If all goes well, the new
>version should include mulitple font loading, hard disk support, and none

>of those silly boot-drive defaults (like OUTPUT.RSC and font files).

     The version if Gdos that we recently received from Atari does indeed allow multiple font loading (from any directory), etc. One thing that i was rather surprised to find was that Ataris version of Gdos does not support NDC coordinates (Landon/Neil can you shed some light on why ??). In any case i feel NDC coordinates are quite useless, and what would be more usable are user defined world coordinates (only metafiles support them), that Gdos converts to RC in the appropriate way so that drawing primitive still come out right (at least on the screen??). Also NDC coordinates are quite useless in Gem as AES does'nt use them anyway. Can someone from DRI/Atari explain why AES was designed in this way (rather why Gem was half done??), or were NDC coordinates added into Vdi as an after thought??

~~~~~~~~~~~~~~~\ lineater, \~~~~~~~~~~~~~~~~~~~~

if you're going to look for ways to cheat, you might try looking in the executable for the rogue's name (i.e. what you type in for the name) that allows you to create anything, scrolls, weapons etc. It's literally right there in front of you in the code. nuff said..

but i agree with you it takes all of the fun out of the game

on another subject; is anyone out there playing Phantasie I ? (if you like rogue, you will fall in love with this game) i have gotten all of the rings and runes and found the black knight's dungeon but i can't get him, what am i doing wrong ?????

    To the person who asked about 'zooming out' in the zoom mode of Uniterm: in the zoom mode, 'Backspace' will restore the previous scaling factors, and 'Return' will leave zoom mode. Also, the arrow keys will move the screen 1/10 of the screen width/height in their direction (in the zoom mode).

Subject: RE: MIDI on the ST
From: Dr. James A. Guffey <GUFFEY@A.ISI.EDU>
To: info-atari16@SU-SCORE.ARPA

> I am considering purchasing an ST and hope to do my own programming to
> use the MIDI ports. Can anyone out there in net-land tell me about
> using the ST with synthesizers and the like? I am a musician as well
> as a programmer and would probably want to write a lot of my own software
> for sequencing, voice editing (specifically Yamaha DX7) and the like.

Mark,

I am also a part-time musician and a full-time computer engineer.
I have two synthesizers and a drum machine that I have had MIDIed to
my ST with no problems. The ST seems to be an excellent choice for this
type of application. Some of the projects I've been working on are a
patch librarian and an Artificial Intelligence based patch generator.
I've also experimented with a single track MIDI sequencer, but nothing
very complex.

> What is a good language to use? I assume C is the best, but which one?
> Can Megamax C be used with the MIDI ports?

I use Megamax C to do my MIDI programming. I've found the inline assembly feature to be very valuable when try to optimize sections of code for speed, a necessity in real-time MIDI applications.

> What about this MacCompatible cartrige that is rumored? Will Mac MIDI
> software run with the ST?

I don't know about this. I would think that the MAC software wouldn't run though since the MIDI hardware interfaces would be different. I don't think the cartridge would take care of this difference.

> If anybody knows anything about ST MIDI software, I would appreciate any
> responses either over the net, or by e-mail.

The following is what is available from Hybrdi Arts...

ATARI 8 bits (130XE, 65XE)
MidiTrack III
MidiTrack III updates (with new book)
MidiTrack II
MMS
GenPatch
Librarians for DX,CZ,RX,Ob8,Pro5,...
Oasis (for EnsonMidiCom (general purpose and MIDI
telecommunication software)
MidiMate Interface

ATARI ST (520 and 1040)

EZ-Track
DX-Droid
DX-Editor
CZ-Droid

****
SOON TO BE SHIPPING----------
ATARI 8 bits (130XE, 65XE, all others)

MidiScore
GenPatch updates

ATARI ST (520 and 1040)

ADAP I (Projected date = Oct 24, 1986)
Sampler and Command Module
Dual Trace Oscilliscope
Echo and Reverb
ADAP II (same or soon after I)

MidiTrack ST (with tape sync interface,

Projected date = Oct 1, 86)
MidiTrack ST Professional (with SMPTE interface, Projected date = Oct 1, 86)
GenPatch ST
MidiUtilities (general purpose file MIDI & TOS, manipulator, perfect for MIDI hackers,...etc.)
EZ-Score (Scores our MIDI song files)
MidiScore Pro (Scores and resequences our MIDI song files)
SMPTEMate (compatible with all forms of of SMPTE US/Euro,...etc., and all tape sync formats (FSK, Roland,... etc). Doubles as MousePad! Projected date = Oct 1, 86)
Oasis ST

****
Hybrid Arts is feverishlg on the ADAP and associated products (20 Software Applications are slated for development).

ADAProcessor) is our "16 Bit Professional Digital Audio Workstation generic digital interface, the software determines the application, that is, ADAP can be a Recorder/Editor, 64 Track Multitrack Recording System (Recorder, Mixer, Effects, Synthesizer,...etc.), Test Sets (Spectrum Analyzer, O'scope,...etc.

ADAP hardware specifications are:

ADAP I - is a 16 bit linear, Stereo (2 discrete channels), +4/-10 dbm in/out, Mic/line at the input, gain trims at the input, calibrated in/out, with LED metering for in/out for calibration and monitoring. It has a sampling rate that is adjustable up to 65k s/s (may change up to 100k s/s), and is fully CD compatible. This version only supports RAM.

ADAP II - Same specs as ADAP I with additional support of "Direct to Harddisk".

ADAP III - (ADAP III is only speculative) Same as ADAP II, but with multiple inputs and outputs (up to 6?).

ADAP can sample up to 20 seconds with an unmodified 1040ST. ADAP tests for available memory, so that, upgrades are taken advantage with an unmodified ADAP. 4 meg allows for about 1 minute sample time.

The sampler will offer 64 samples key assignable, 6 voice poly,...etc.

The direct to disk versions can record up to 40 minutes or more! The 2 track editing capabilities are going to be astounding, and ultra-easy!!!!!!!!!!!!!!

The ADAP has made its first television and live stage appearance.

The television show was "Chronicles" aired on your local PBS station during the week of September 29, 1986. Call "Computer Chronicles" at; 415-574-6233 and ask about the "#403, MIDI Music" segment, or request transcripts via "Compuserve". Hybrid Arts presents the ADAP and EZ-Track to the world.

smb: I called the "Computer Chronicles" people and they said the show would air again during the week of DEC 23. CAll your local PBS station for the exact time.

The "Pointer Sister's" used ADAP, live onstage before 17,000 listeners. In the crowd were: Sam Tramiel, Gary Tramiel and other executives from ATARI, Wendel Brown, Rick Oliver and Scott of Hippopotomus Software, all invited by Hybrid Arts. Afterf the show the Tramiel's were taken backstage and introduced to the "Pointer Sister's".

****
Enough of ADAP, EZ-Track is our $65, 20 track MIDI Recorder, with lots of advanced features that has been shipping for about a month now. It can be bought through our music dealers and "Mega-Chain Stores" like Federated,...etc.

DX-Droid for the ST is shipping, it will actually program you DX/TX modules for you ($244).

CZ-Droid for the ST is shipping ($99), it will program ALL CZ's for you (even the unprogrammable 230S, that's right! and the CZ1).

EZ-Score for the ST ($99) will be shipping soon, it will chart out our song files for you (like printing the standard musical notation for your EZ-Track songs,...etc.)!

SMPTEMate, a universal SMPTE interface for the ST will be shipping October 1, 1986. This incredible device will read and write all standard forms of SMPTE and lock up to all other forms of presently used tape sync (like FSK,...).

All associated manuals can be bought separately.

I called Hybrid Arts and the price of the ADAP I is listed at $1995. MIDITRACK ST is $375/$575(with SMPTE). Also I know Dr. T's has just released a MIDI sequencer for $199. With this kind of support, the has a good chance of becoming THE computer for MIDI applications.

To: info-atari16@score.stanford.edu

How did you get GDOS from Atari? When I called the other day, they told me
that either I had to pay the $500 licensing fee per product per year, or I
could send my software that didn't use GDOS to them "for testing". I was told
that if I wanted to do that testing myself, I should buy some commercial
software that has GDOS on the disk and use that copy.

Can anyone shed some light on this?

Subject: Re: Micro-EMACS 3.7i -- bugs and comments
To: info-atari16@su-score.ARPA

I think some people misunderstood my point about the search string delimiter key. I'm not pitching for using a machine-specific key like ENTER or control-RETURN. I would like to use RETURN itself (which is about as standard as you can get). The point is that given ^Q-RETURN inserts a <NL> anyway, why not use RETURN to delimit the search string rather than ESC? I have worked with fairly lay people and nearly all of them find ESC very non-intuitive. If this is to be an editor for a user-friendly PC for non-technical people, RETURN makes much more sense as a delimiter (besides being easier to type). I guess the best thing to do would be to make it customizable, as a couple of people have already suggested.

The other related point is that ^M should insert a ^M rather than being coerced to <NL>. Since <NL> is merely ^J, either ^J and ^Q-RETURN can be used to get a <NL> in the search string.

Finally, for those who haven't managed to bind their mouse, try:

```
    bind-to-key previous-line      FNH
    bind-to-key next-line          FNP
    bind-to-key forward-character  FNM
    bind-to-key backward-character FNK
```

(I also find it useful to bind the left mouse button to SET-MARK; to do this, try: "bind-to-key set-mark FNt"). One question though: it is weird to see the cursor wrapping around when you move the mouse off the left or right end of a line (again, something I could live with but non-intuitive nevertheless). Is there a way to define a macro that would not do that, and bind the mouse key to that? Something like the LOOKING-AT function of Emacs with some sort of conditional would do it. (Unfortunately, I still can't RTFM. No-one sent me one. Sigh...)

Subject: AUTO folders
To: info-atari16@score.stanford.edu

<< Why is there a line eater? Well, bec

I've got a problem with AUTO folders. I wrote a simple program to
set the time and date using Mark Williams C. I then put it in my
AUTO folder. The problem is that it sometimes exectues the folder more
than once! I boot up (or reset) and it loads and runs the contents of the
AUTO folder 2 or 3 times. It runs the AUTO files only once about 2
times out of 3, but that third time it runs them multiple times. I
think I have exitted gracefully (with the exit() routine) so I am
confused.

Any help would be greatly appreciated.

Subject: More on GDOS

Neil:

So you say GDOS is ready. That is good. When is it going to be made available
to everyone? Is GDOS going to be available as a product sold by itself?
Is the first version going to be able to get along without reading files off
a floppy disk?

Speaking of running without a floppy, when might we get software to let us
boot off of our hard disks?

While I am on a roll here, is the next version of TOS going to fix the famous

40 directory limit? Is the version of TOS in the new ROM's (the ones that will go with the Blitter chip) improved in terms of fixes/additions?

BTW, the return address of getty@prandtl on my last note was caused by malfunctioning software, and was bogus.

Thanks in advance,

Karl

P.S. If GDOS is ready, release it to the masses now!!

Subject: Printable Character Archiver
To: info-atari16@score.stanford.edu

I (with some others) am in the process of building a printable character archiver, called "earthpig" (it's an aarchiver, :-)). The following is an example of the compression its printable character encoding algorithm gets.

The "test" file is /bin/vi. I have shown the compression ratios for the various interesting files. A file ending in "pig" is an earthpig encoded file. A file ending in "uue" is a uuencoded file. A file ending in 'Z' is a "compress"ed file.

```
test     131338
test.Z         70103   (0.533 of test)
test.pig 143087   (1.090 of test)
test.uue 180979   (1.378 of test)
test.pig.Z     73175
test.uue.Z     94691
test.Z.pig     96698   (0.736 of test)
test.Z.uue     96611   (0.735 of test)
```

For compressed data, it does about as well as uuencode. For uncompressed data it's quite a lot better. Small binaries (under 20K) shrink slightly. C programs and text files shrink slightly or stay about the same.

Earthpig uses only the characters

```
     +-abcdefghijklmnopqrstuvwxyzABCDEFGHIJKLMNOPQRSTUVWXYZ
     @.,;:=?*"'/!()_%&
```

This character set should make it through almost anything unchanged. The algorithm only uses table lookup: no bit masking or shifting.

When we finish the archiver we will post various versions of it to the net.

What it does:

- can generate correction requests from errors
- can generate patches from correction requests
- CRC checking on two levels
- supports os independent hierchical file names
- high immunity to format changes and noise characters (space/control)
- close to 1:1 encoding on uncompressed data

The basic goal of earthpig is to provide a single tool that will allow the transfer of arbitrary data and software around the network while providing a very high level of confidence that the data arrived correctly.

>(remember: from now on, pointers are 32 bits, until they get to be 64!)

I DO remember, and I HAD already tried that method, and it ONLY prints
out the first 16 bits. If anyone can actually get it to print the full
32-bit number I should like to know (maybe %d would work).
BTW, I note in my tests that malloc can actually hand out blocks larger
than 8K. Any problems with this, since at least one of my correspondents
thought that 8K was the maximum.

Another bug, though maybe not Megamax. If I try to use the editor to
look at a file which is too large to fit into memory then I get a nice
dialogue box telling me so, but no amount of mouse clicking gets rid
of that dialogue box.

Subject: CP/M-80 Z80 Emulator Bug
Message-ID: <1429@hcrvx1.UUCP>
Date: Mon, 10-Nov-86 18:01:24 EST
Article-I.D.: hcrvx1.1429
Posted: Mon Nov 10 18:01:24 1986
Date-Received: Tue, 11-Nov-86 00:33:45 EST
Organization: Human Computing Resources, Toronto
Lines: 52

I have just spent some time putting up the CP/M-80 emulator on my
1040ST. I have found the emulator seems quite well done. But there
are some problems with it.

In the Z80, there are two flags for purposes of BCD arithmetic: the
H flag is for recording "half-carry" and the N flag is for recording
whether the last operation was an add or a subtract. An AND
instruction sets both N and H flags. Similarly, an OR instruction
clears both. (In the 8080, there is no N flag, and both the AND and
OR instructions clear H.)

In the emulator, the AND and OR instructions seem to leave the N and
H flags alone. So it does not match the Z80, or even the 8080.
Although this seems unimportant, I only discovered it because it
caused the program that I was porting to fail.

The emulator seems to support only floppy drives. I could not get
it to use a RAM disk (I use the Intersect RAM disk at the moment).
Since the disks it uses must have a CP/M file system, I don't wish
to try my hard disk. Even on a floppy, it only supports a single
side! This makes the emulator much less useful on a system with
only one floppy drive.

The make_cpm command (to start the bootstrapping process of creating
the first CP/M disk) prompts at the start. DO NOT put the blank
disk in at this point. It needs to fetch a file from the TOS disk

(which must be on a floppy, I think). Put the blank disk in at the second prompt. If you do put in a blank disk the first time, you will not get a diagnostic. The machine will just fall asleep for a minute and then return to the desktop.

I sure wish that the TOSCPM and CPMTOS commands (for transferring files between TOS and CP/M file systems) would take ambiguous file names. As it is, a command must be issued for every file transferred.

I don't see a way to change what terminal the console emulates. My ST is replacing a Kaypro II. But since the Kaypro emulates an ADM-3 (more or less) and the ST emulates a VT52 (more or less), I cannot trivially move my programs. (Legality is another problem, but I am not talking about copyrighted programs.)

The emulator is not quite good enough to be useful to me. Just a few enhancements could change this.

Now that this program is free, I wonder how much support will be provided by Atari or the original developer (a company in West Germany).

Would anyone know if and when BORLAND is planning to come out with TURBO MODULA2 for the Atari ST series? I would also appreciate comments on TDI's MODULA2 developper's package for the ST.

Thanks,

Jean-Pierre Corriveau

>are some problems with it.
>
>The emulator seems to support only floppy drives. I could not get
>it to use a RAM disk (I use the Intersect RAM disk at the moment).
>Since the disks it uses must have a CP/M file system, I don't wish
>to try my hard disk. Even on a floppy, it only supports a single
>side! This makes the emulator much less useful on a system with
>only one floppy drive.

I have had no problems with running the emulator off of a ramdisk. Using the inidir.com program included in the package, I have been able to reinitialize ram disks previously set up under TOS for CPM. The ramdisk I am using is one I downloaded off of a local BBS, and has no documentation, so I do not know which one it is . It is a fixed 600k Ram disk.

In an in store experiment, I have tried running the emulator off of 1 partition of the Atari 20mb Hard Drive, with seeming success. (Just imagine: A system with Magic Sac, the CPM emulator and the ST, all running off of different partitions of the same Hard disk!)

>The make_cpm command (to start the bootstrapping process of creating
>the first CP/M disk) prompts at the start. DO NOT put the blank
>disk in at this point. It needs to fetch a file from the TOS disk
>(which must be on a floppy, I think). Put the blank disk in at the
>second prompt. If you do put in a blank disk the first time, you
>will not get a diagnostic. The machine will just fall asleep for a
>minute and then return to the desktop.

     Further advice. people with 1040st's should boot off of a
SINGLE SIDED diskette before attempting the installation program. This
seems to make a diffence.

Keywords: Which is better in your opinion?

Recently I have been debating whether or not I should purchase MT Micro C Shell
or OS9. Both are said to have the feel of UNIX, both are said to have
multi-tasking and multi-user capabilities, both of which I highly desire for my
Atari ST [it would make me use my Macintosh less, but I'd be willing to pay the
price!]

How many of you netters have had experience with either or both OS9 for the

Atari ST, and MT Micro C Shell? I probably would have make a hasty decision
long ago if either were readily available in the beautiful Land Of UM
[Upper Montclair, NJ for those of you not in the know]

Please reply via email and if there is enough interest, I will post my
findings to the net.

ciao for now,
     gib

Thanks for this info. I was agonizing over whether to buy an Atari or Amiga.
I loved the old Atari color monitors, but the built-in sound is also the pits.
The Amiga has reasonable sound and other interesting features, but the display
was not as good as the Atari. (The price difference was not an overriding
concern.) Now Atari has solved my problem. I can my cake and eat it too!

Bye, bye Atari. Buy, buy Amiga.

------------ Plop Plop Fizz Fizz --> Line Eater --------------

Hi. I suppose since I started the C++ round, I should answer the
question about its availability. C++ is not (as far as I can tell
and have been told) in the public domain. AT&T gives licences out at
around $500.00 a crack so I've heard. Furthermore, as far as I know
there is no micro verxion for the Atari even from them. I may be
wrong. Anybody who has other information please correct me, and
write me. It's too bad, since C++ is a great extension to C, and
would not be too hard to port over (software companies take note:
I'd surely buy a copy of C++!).
   As to its availability on the VAX, that is the only place I have
ever heard of it. Once again, I think you must contact AT&T.

Now, on another topic: I just got a new game the other day, Star
Glider. It is really great. Nice graphics, an interesting scenerio,
and even music in the beginning! A good game. John says:

     /
       V Check it out.

One last thing before I go: I missed the Uniterm posting for
unknown reasons. Can anybody e-mail me a _working_ copy? Thanks in
advance.

Net.sources used to have the same problems as net.micro.atari16 with
regards to large postings producing hundreds of requests for retransmission.
One person (I think it was Bill Mitchell of U. of Arizona) said he'd
never again post any big thing to the net because it was weeks of hassle
straightening it all out. Then he released a revised version and had to
face it all again...so he send it to mod.sources

The mod.sources moderators keep careful watch on their news links, and
have arranged for each posting to appear simultaneously on many
machines around the net. This significantly reduces the chances of
your getting a truncated copy, or no copy at all, since the message
will have to go through less hops to get to you, and if one site drops
it, another will carry it to you. Also, just having the moderator
check the message to see if it will download, reduces the trash by a
large factor.

This takes work, however, and requires a site with good news links (or
that is willing to make a set of good cross country links for shipping

the newsgroup out to the world). Reliable mail is also essential, since all the postings will come in to the moderator by mail. I suggest that the Atari community find a person at such a site to handle distribution of large Atari sources or binaries. Ideally this person is already a PD software packrat, so they know what they are getting into. The moderator should also have good bit of disk space [on their Unix machine] for archives of what's been posted.

I don't think there would be much complaining from the netghods about creating mod.atari16.sources and binaries groups, given a willing moderator.

As for IBM machines not knowing what their character set is and messing up postings, I suggest that the BITNET sites involved submit an APAR to IBM complaining that their operating system should support ASCII as an alternative to EBCDIC, and see what they say. [I don't mean supporting ASCII terminals! I mean supporting ASCII as the internal character set for files, commands, etc.] While, even if IBM agrees, it will take years, you have to start sometime...

I am getting tired of these networks. My copy did not work, after all the undecoding, ARC decided I had a bad header. Could someone post UNITERM.ARC to a BBS *anywhere* in the Continental US? Atari BBS is more than fine. From there, others like myself will be able to download it and un-arc it. (Be sure to leave a copy of ARC at the BBS where you upload it, if they don't have it there) Thanks.
Rick

From >Expert Systems<, July 86, Vol.3, No.3:

The Lisp/ST system from Robinson Systems provides- for under 1,000 pounds- an AI workstation with 1Mbyte of RAM and disk, 640x400 high resolution graphics, mouse and Lisp software.

Lisp/ST is a version of Common Lisp, providing a development and runtime environmentincluding multi-window support on the GEM operating system. Functions for pretty printing and debugging Lisp programs are included with the package. Lisp/ST is written in the language Modula-2 and can, the developers claim, easily be ported to other operating systems and computers for OEMs.

The Lisp/ST software system costs 99.95 pounds. A complete AI workstation based on the Atari 1040/ST computer with Lisp/ST software is available for 899.00 pounds.

Robinson Systems Engineering Ltd, Red Lion House, St. Mary's Street, Painswick, Gloucestershire, GL6 6QR, England. Tel:(0452)813699.

I mistakenly subscribed to Personal Computing before I bought my ST. My
personal opinion is that they think if it isn't a PC or Clone or a Mac
its not a personal computer. They have made almost no mention of either
the Amiga or ST since I started buying this mail box filler. (I don't
plan on resubscribing.)
Personally, asfter reading this magazine for about 6 months is that IBM
has done for PCs what they did for mainframes. Made them unnecessarily
hard to use.

I've been using a Teac 5.25" drive for about a year now. It works flawlessly without changing the access rate or using a buffer chip. This seems like the drive to use if you need a 5.25" drive.

If you want to upgrade your original single sided 3.5" Atari drive to a double sided drive, I have been told that Epson 3.5" drives work quite well. There are only
two problems. First, the busy light is on the wrong side. You'll have to remount it, or just listen to the drive if you want to see if it is on. :)
Second, the disk eject button is too short to reach through the Atari drive's cabinet. To fix this, you need to replace the eject button on the new drive with the one from the old drive.

I am planning on doing this upgrade soon, so I'll let everyone know how it goes.

Keywords: It still doesn't work

I downloaded the second executable for version 3.7 of uemacs last
week. I could not get it to work. Its decodes without any problems,
but as soon as I try to run it, it runs and exits before anything
can happen.

I downloaded the earlier version posted in about July, and the same
exacted thing happened. I rarely have any trouble with sources, so
there must be something about uemacs that my machine does not like.
I have a 1040. I have not had any problems with other big programs
like hack or uniterm that I've pulled off the net.

Any ideas? Could it be the resource file? I didn't think they were
supposed to be straight text.

HELP!!

Thanks,
Phil Paone

XXKKiillll those double characters!
XX
XXI finally got tired of the horrible sounds my C.Itoh 8510A printer is doing,
```

```
XXwhen printing proff'ed documents in incremental print mode. To cure the
XXproblem, I've written a simple filter to convert overstrike sequences to
XXthe corresponding printer control codes. As there have been some requests
XXfor such a utility, I'm posting the program to the net.
XX
XXThis is a true filter, i.e. reading from stdin and writing to stdout. Watch
XXout for the problems, that Megamax-C is having with I/O-Redirection. The
XXTTP-Application runs fine from the DESKTOP and any COMMAND shell, that
XXdoesn't do redirection of its own. I ran into problems with the COMMAND.PRG,
XXthat comes with the developers kit and the Michtron shell. I suspect problems
XXwith the Beckmeyer shell, too. The filter works nicely with the COMMAND.TOS,
XXthat has been posted by franco@iuvax (thanx a lot!) many months ago.
XXBTW: Lattice-C is also doing I/O-Redirection of its own. Expect similiar
XXproblems as with Megamax-C.
XX
XXThe filter does a little more than is absolutely necessary. I suppose it can
XXhandle nroff output, too. But this hasn't been tested, yet.
XX

XX/* rmbs.c   (V.1.0)
XX *
XX * Rmbs converts the output of text formatters like proff or nroff
XX * (not tested) into a form that is less harmful to the mechanics
XX * of a modern matrix printer. These formatters highlight text by a
XX * technique called overstriking. Rmbs tries to detect the character
XX * sequences that are output for bold, bold and underlined and
XX * underlined text and converts them to the corresponding control
XX * codes of the printer.
XX *
XX * Proff outputs the following sequences:
XX * Bold:              'char' '\b' 'char'
XX * Underlined:        '_' '\b' 'char'
XX * Bold & Underlined: '_' '\b' '_' '\b' 'char' '\b' 'char'
XX * This implies an ambiguity that cannot be easily resolved: What
XX * does '_' '\b' '_' stand for? Is it a bold or an underlined '_'?
XX * For ease of coding I've decided, that it's a bold '_'.
XX *
XX * Because the printer control codes are hardwired into the program,
XX * you must build a different version of the program for every printer
XX * you have. As most people (including me) have only one printer, I
XX * didn't want to bother with a suitable data base of printer codes.
```

```
XX *
XX * Although there's a high probability, that there's no true original
XX * idea in this program, you should give me credit, if you debug,
XX * modify, enhance, or give it away. Lightning shall strike your
XX * computer(s), if you sell this program or any close derivatives
XX * for profit.

XXShar/Unshar for the ST!
XX
XXSome of you have been requesting a program to unshar USENET postings on the
XXAtari ST. I finally could spare some time to port such a utility to the ST.
XXIt has been written by Dave Wecker and was posted to mod.amiga.sources some
XXtime ago. (It pays off to look into other news groups, too :-)
XX
XXI've tried to keep its original functionality: It should still work on UNIX,
XXVMS and the Amiga. The Atari stuff is new and has been done by me. It does
XXcontain #ifdef's for Megamax, Lattice and DRI-C. It has never been compiled
XXwith the dev-kit compiler, because wild cards on the command line are a sure
XXway to bomb every DRI-C program (look for the comments in the source). The
XXprogram runs fine, however, when compiled with Megamax or Lattice. (Beware
XXof bugs in the Lattice V.3.03 library!)
XX
XXIt's a great tool, that should be on every netlander's utility disk: Nice for
XXUNIX folks (transfer only one file instead of many) and a real life saver
XXfor all (poor) BITNET and VMS hackers, who don't have access to the Bourne
XXshell. However, this program is not a REAL shell!
XX
XXIt will unshar most of the common shell archives (cat- and sed-type). But it
XXstill has problems with some of the bizarre formats Rich $alz (moderator of
XXmod.sources) has been posting lately. He's assigning file names to the shell
XXvariable $OUT and unpacking on the ST ends up with only the last file of the
XXarchive being put into the file $OUT. Stop him doing such strange things :-(
XX
XXAs all the CLI's for the ST (at least all I know of) don't do wild card
XXexpansion, I have included a routine of my own. Drive specs, directories and
XXambigous path names are accepted. Say 'a:', 'a:\', 'a:*.*', or 'a:\*.*' to
XXshar all regular files on drive A. Or say 'megamax\headers', 'megamax\headers\',
XX'megamax\headers\*.*', or 'megamax\headers\*.h' to pack all header files of
XXthe Megamax compiler into an archive.
XX
XXShar output usually goes to stdout and can be redirected when calling the
XXTTP-application from the desktop. As everyone probably knows by now,
XXMegamax and Lattice programs want to do I/O-redirection of their own and
XXcome into real problems when the redirection is done by a CLI. That's why
XXI've added an additional -o option to the shell archiver. Use '-o outfile'
XXinstead of '>outfile' and you're not going to have any problems. (Well,
XXdon't flame me, iff you do get some problems. Send mail instead.)
XX
XXI'm including the README file of the original posting, too. Maybe someone
```

```
XXis having a ST [real workhorse] and an Amiga [nice game machine].

SHAR_EOF
if test 13843 -ne "`wc -c SHAR.C`"
then
echo shar: error transmitting SHAR.C '(should have been 13843 characters)'
fi
echo shar: extracting README.AMG
sed 's/^XX//' << \SHAR_EOF > README.AMG
XX
XXEnclosed is a first version of "shar.c" (v 860712 DBW) that will run on
XXULTRIX (U**X 4.n), VMS and the AMIGA. I finally got fed up with ARCV
XXMKARCV and decided to do things right.
XX
XXThe main item of interest is that it handles wild-cards on the AMIGA and will
XXalso UNSHAR a file (for the AMIGA and VMS which don't necessarly have
XXthe Bourne Shell). It will NOT create a SHAR file with sub directories. The
XXAmiga version was done with MANX-Aztec-C, it probably needs some changes to
XXrun under Lattice.
XX
XX/* Moderators note:  This program will allow interchanging shar formats from
XX * Unix and the Amiga.  I have tried several Unix shar formats and they have
XX * all successfully unshared using this program on the amiga, and this will
XX * also create shar files that will unshar under Bourne Shell without any
```

```
XX * problems.
XX */
XX
XX                regards,
XX                dave (ucbvax!decwrl!cookie.dec.com!wecker)
XX
XXCreating a shar file:
XX
XX   AMIGA:   shar >foo.shar -a makefile *.h *.c
XX
XX   VMS: create a batch job that executes:
XX        $ shar -a makefile *.h *.c
XX        edit the batch .LOG file (which is your shar file)
XX
XX   U**X:    shar -a makefile *.h *.c >foo.shar
XX
XX        (P.S. the -a switch means do all options)
XX
XXExtracting from a shar file:
XX
XX   AMIGA:   shar -u foo.shar
XX
XX   VMS: shar -u foo.shar
XX
XX   U**X:    shar -u foo.shar   or    sh foo.shar
XX
XX
XXInstallation:
XX
XX   AMIGA:   cc -DAMIGA shar.c
XX        ln -o shar shar.o -lc
XX
XX   VMS: cc/DEFINE=VMS shar.c
XX        link shar,sys$library:vaxcrtl/lib
XX        shar :== $dev:[dir]shar
XX
XX   U**X:    cc -O -DULTRIX -o shar shar.c -lc
XX
XX
XXJust typing "shar" will yield a usage line. (Doc: thanks for the code to
XXbase this off of).
XX
XX
SHAR_EOF

Summary:

I mentioned in a previous article that I had written some arbitrary 8 bit encoding programs that I could easily turn into an archiver specifically designed for network transfer. Since there seems to be some interest in the topic in general, I'll tell you what my programs do.

In the most general case, my encoding routines are given a list of characters that the transmission medium does not want to see. It will then never generate those characters. It accepts a stream of arbitrary 8 bit bytes, and produces an encoded or decoded stream.

The actual encoder operates in two modes: eight bit encoding (M8) and seven bit encoding (M7). The encoder decides what mode it should be running in, depending on the cost of the mode.

In seven bit encoding mode, any seven bit character can be transmitted. Any character the encoder has been told is pathological is mapped into a two character escape code. This mode is obviously very cheap for text. Any transmittable character is sent as itself.

In eight bit mode, the encoder can accept any 8 bit value. Each group of three input bytes is turned into four output 6 bit values. These six bit values are then mapped onto the ASCII characters "a-zA-Z,.".

Run length encoding is performed in both modes.

The archive format I was considering would have a special archive control character (something non-controversial) which would never be generated by the encoder. The archive control characters would signal the beginning

of easily parse text strings that would describe the beginning and end
of archived files, their CRC's and lengths. It would be possible to
generate checkpoints in the archive. The archiver could extract all
undamaged files from an damaged archive.

The checkpoints could be used for retransmitting parts of the archive. If
an archive was damaged, the archiver could tell the user what part of the
archive it needed replaced. Anyone else who had a complete archive could use
that information to generate just the data needed to repair the broken archive.

The archiver will treat a set of unordered files as an archive. Each
file would be searched for a header. The header would identify the archive
and be used to order the parts. It would then read the files in the
correct order. The archive creation command would automatically generate
a numbered set of files for posting, according to a maximum size constraint.
No more editing and cat'ing of news articles.

My experiments show me that this program encodes a.out files slightly more
cheaply than uuencode, text files are very cheap. The experimental version
does not transmit any of the following characters: all control characters,
"<>{}[]^|\\~", and del.

If there is any interest, myself and another fellow here, Mike Gore, will
put this together out of code we already have (for encoding, CRC checking)
and we will post the source (for UNIX and Atari) and uuencoded versions for
the Atari ST.

It would be written to be portable.

Comments?

Keywords: Only ONE try!

OK - in response to many requests, I am posting the binaries to my Vi editor clone VIX. This is one last try at posting a big binary posting on this net group. I WILL NOT repost, I I would request that others do the same. Let's give it a try. If it fails, we will wait till the mod group is formed to do this sort of thing.

The posting will follow in 3 parts. Parts 1 and 2 are a split uuencoded file - about 40K bytes each. This should be well under the choke limits at most places. Since this is a uuencoded file, some sites may barf on the {}'s, but so it goes. Part 3 is some documentation, suitable for printing as is, but without any pagination.

Please direct any comments/suggestions to me. If this posting chokes at too many places, I will wait for the mod group before trying again.

Note that the sources are avaiable on 2 single sided or 1 double sided atari disk. Send me a pre-formatted disk + return postage or $3 handling, and I will send you the complete sources for the VIX version, plus the native TVX version. All the stuff needed for a UNIX or IBM-PC port are included.

Keywords: Documentation

This is the documentation for VIX. Please note that VIX is NOT an exact work-a-like, but pretty darned close for the most often used commands. You will be comfortable using it.
------------ cut here for documentation ---------------------

VIX Reference Manual

This is the Reference Manual for VIX, a full screen editor written in C by Dr. Bruce E. Wampler. (Current address: Dr. Bruce E. Wampler, University of New Mexico, Department of Computer Science, Farris Engineering Center, Albuquerque, NM 87131; uucp: ...{ucbvax | gatech | ihnp4!lanl}!unmvax!wampler). Any comments, bug reports, or suggestions should be sent to that address. Full source code is also avaiable.

VIX is NOT Vi, but a close emulation based on the editor called TVX. While the majority of the common commands are identical, there are some inherent differences in the way TVX and Vi treat text. Whenever possible, VIX emulates Vi commands exactly. When that wasn't possible, the emulation won't produce a surprise, or will be implemented as a completely different command name. (Mostly as 'q' prefix commands.) None of the underlying ex commands are avaiable.

This version of VIX Copyright (c) 1986 by Bruce E. Wampler. Permission is hereby granted for free, unrestricted nonprofit use of this software. Please feel free to modify, distribute, and share this software as long as you aren't making any money from it. If you want to use this code in a profit making environment, please contact the author for permission.

********* General Notes

Most commands also take an optional numeric count. The default count is always one. Commands that allow a count value are preceded by the letter 'n' in the following descriptions. Whenever a command produces output or an error message, it appears on the bottom line of the screen.

The BACKSPACE key (Control-H on some terminals) is used to edit input text. When VIX is accepting commands, BACKSPACE will cause the character immediately before the cursor to be deleted.

Vi uses the ':' command to read and write the file (among other things). Vix uses the ':' to set operating parameters such as autoindent, screen size, etc. The 'ZZ' (or 'ZA' to abort without changes) command is used by vix to exit.

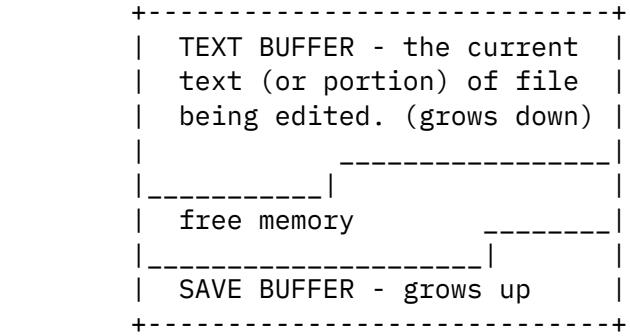
Vix does not have the underlying ex editor, so none of the escape to ex commands work. Vix does have the TVX repeat loop, however, and this compensates to a great extent for the need for ex features. Please consult the TVX manual for examples of using the repeat loop. Note that when using the repeat loop with vix, the commands will be vix commands and not tvx commands.

VIX uses two techniques for protecting the original file from editing mistakes. First, each time a file is edited, a new version is created, and the previous version retained in its original form as a backup. This file will change the original file extension to '.BAK'.

***** The Text Buffer and Moving Text

The VIX emulation works entirely in the available memory for editing. The text from the file which is being edited is held in a buffer in main memory. If a file is particularly large, it may not entirely fit into main memory. The buffer size limit in no way restricts the total size of a file that can be edited by VIX. To make editing large files easier, some commands apply to the entire file and cause automatic cross buffer manipulation.

VIX actually divides the internal memory into two parts: the text buffer and the save buffer. The text buffer (or simply the buffer) is used to hold the file (or part of the file) being edited. There is only one such text buffer. The save buffer is used for moving text, both from one part of the text buffer to the other, as well as to and from external files. The maximum size of the save buffer depends on the amount of text currently residing in the main text buffer. The following diagram shows the internal VIX memory organization:



Text is added to the text buffer when the file is first read in (or created). If the file doesn't fit into one buffer, you will have to manually "page" the text into the buffer. Text is added to the save buffer in one of several ways. VIX has added commands to move text from the text buffer to the save buffer, and move the contents of the save buffer to the text buffer. VIX also has "cut mode". When cut mode is enabled (the default), when lines are killed, they are automatically copied into the save buffer as well as being deleted from the text buffer. When off, deleted lines are not saved.

It is also possible to save the contents of the save buffer to a new external file, and to load the save buffer from an external file.

'P' and 'p' are used with 'y' and '^Y' to move text around. 'P' causes the text in the save buffer to be inserted before the current cursor position. 'p' is used to insert the save buffer after the current line. The saved text remains in the save buffer.

The 'y' command command will yank (save) the current line in the save buffer, and move the cursor down one line. On the screen, 'y' appears to have the same behavior as 'j'. If n is supplied, then n lines will be yanked. 'y' can also be used sequentially. If no other commands intervene, consecutive 'y' commands will continue adding lines to the save buffer. If any other commands are entered between consecutive 'y' commands, the previous contents of the save buffer will be lost, and replaced with the new line. If cut mode is on (the deault), a 'dd' will overwrite the save buffer! The 'Y' command can be used to append lines to the current save buffer without losing the previous contents.

The 'd/' command can be used with 'y' 'Y', 'P' and 'p' to move text. Use 'y' to save the text to be moved, immediately delete the saved text with 'd/', then insert it at the new place with 'p' or 'P'. The last line of the file is can be saved in the save buffer only once, and an error message will be printed if you attempt to save the last line a second time.

A 'qy' is similar to 'y' yank, but the text saved in the save buffer is read in from an external file instead of from the text buffer. When 'qy' is entered, the save buffer is cleared, and the user is prompted for the name of the file to read. VIX then will read as much of the external file into the save buffer as it can. The 'P' or 'p' command can then be used to insert the save buffer text into the current file at the desired location. If there is not enough room in the save buffer to hold the entire file, then only part of the file is read and a diagnostic message printed.

A 'qp' causes the contents of the save buffer will be written to a new file. After 'qp' is entered, you will be prompted for the name of the output file, and then the contents of the save buffer will be written to that file.

The 'qw' command is used to explicitly go from one buffer to the next. By default, when n is >= 0, the entire current buffer is written to the new version of the file being edited, and the next buffer full of the original file (if any) is read in. If a negative n is supplied (any negative value, most easily '-qw'), then only the part of the buffer up to (but not including) the current line is written. Then as much more of the file as possible is read to the end of the current buffer. Thus, a negative n is useful when a file won't fit, and the split point is at an awkward place. It is also useful when a 'qy' yanked file won't fit.

***** Searching

Unlike Vi, end of lines are not special to VIX. Thus all the cursor movement commands and delete single character commands will treat the end of line as just another character. This also means that a <Return> (end of line) is a valid search character, and thus makes it impossible to end a find pattern with a <Return>. The <Escape> key is used to mark the end of a find pattern. VIX also supports find pattern wild cards somewhat different that standard VI.

Another basic concept of VIX is the "last thing." Whenever VIX finds a pattern from the search command, skips over a word, or gets from or puts to the save buffer, that text is considered the "last thing." The 'd/' will delete the "last thing".
While this is this a powerful editing concept, it does have some consequences. First, the cursor will always be placed AFTER the pattern just found.

The search normally ignores the case of the letters in the pattern. If the 'q:f' parameter is set with 0 ('0q:f'), then search command will match only the exact case. If the pattern is found, then the cursor will be placed immediately following the pattern. The pattern may be at most 100 characters long.

VIX supports extensive wild card matching. The 'q:m' set parameter controls whether or not wild card matching is turned on. Normally, it is. The wild card matching in VIX is based on the concept of 'sets of special characters'. VIX predefines 6 sets of characters, and allows the user to define one additional set. When a special control character is included as part of the find pattern, then any character in the specified set will match the pattern. The predefined sets are:

```
^A - Alphanumeric characters: a-z, 0-9
^D - Digits: 0-9
^L - Letters: a-z
^O - Other characters: all characters except a-z, 0-9
^P - Punctuation: '.', ',', '!', '?'
^X - Any character: any printable character
^U - User character: any character in user set, set by ':U'
```

Any of the sets may be specified by entering the proper control character in the find pattern: Control-A for the ^A set. Thus, entering a find pattern of '^L^D' would match any letter followed by any digit. Since it may be desirable to match a sequence of one of the character sets, two prefix characters are supported. A '^W' before one of the above sets will match a 'word' of that set. Thus, '^W^L' will match any word, and '^N^D' will match any number. The find pattern 'st^W^L' would match words starting with 'st'. The '^N' prefix is used to make a 'word' of characters NOT included in the given set. Thus, '^N^L' will match a 'word' of characters NOT including the letters a-z. A match 'word' consists of any sequence of

characters (at least one character long) found in the given set, up to the first character not in the set. End of lines also terminate all wild card patterns. The only real way to adequately understand VIX wild cards is to use them in practice.

The last pattern found with the find command (up to 100 characters) is saved in an internal buffer. The '*' command will insert that pattern into the text at the current cursor location. If the last find pattern included wild card characters, the pattern saved will be the actual text matched, and not the wild cards themselves.

'q/' is the same as '/', except the search will cross buffer boundaries. Whenever a buffer is searched without finding the pattern, the next buffer will be read in. The screen will not change until the pattern is found or the file is exhausted. If the pattern is not found anywhere, then the entire file will have been written out, and there will be an empty buffer. The 'qb' command may be used at that point to get back to the beginning of the file.

***** Repeat loops

Probably the most powerful editing tool provided by VIX is the repeat loop. This allows arbitrary command sequences to be entered, and repeated any number of times. VIX will have at least 5 different repeat buffers. The repeat loop is used instead of the standard Vi macro command facility.

When 'n<' is entered, the editor echoes 'Repeat: n<' at the bottom of the screen. The user then types in any series of commands to be repeated n times. The repeat command is terminated with a matching '>' and a double escape (echoed as $$). Repeat loops may not be nested. The repeat loop has two typical useful functions: one is to replace multiple occurrences of a string with another (e.g., "10</onec/two>$$"), a second is to save a complicated sequence of commands to be repeated as necessary with the '@' command (i.e., a macro facility). Each repeat loop may have up to 100 characters.

When a repeat loop is entered from the keyboard, it is saved in one of 5 repeat loop buffers, each identified by an integer value. The repeat buffer which is currently in use can be set with the 'nq:r' command. Buffer 1 will be used by default.

The '#' command has been provided to simplify the use of the multiple repeat buffers. Entering '23#4' for example, will cause repeat buffer 4 to be executed 23 times

When making repeat loops, it is easy to make a mistake. The 'qe' command allows any of the repeat buffers to be edited, and then the 'qr' command can save the corrected repeat buffer back. If you don't give a value for n, the currently selected buffer is used.

The 'qe' command will insert the contents of the selected repeat buffer into the current text buffer above the current text line. The repeat buffer will start with a sequence of '#n:<', where n will be replaced by the repeat buffer being edited. The '#n:' identifies which buffer you are editing, and is used by the 'qr' store repeat buffer command to identify the buffer to save to. Escapes will be represented by '^[' instead of the '$' used when entering a repeat buffer initially. A '>^[^[' identifies the end of the repeat loop.

After you have edited the repeat buffer, it can be saved with the 'qr' command. You must place the cursor anywhere on the first line of the repeat buffer before using 'qr'. When you press 'qr', the buffer will be saved in the buffer indicated right after the '#'. Thus, unlike 'qe', the 'qr' command accepts no n value.

***** Settable parameters

Many of the basic operating characteristics of VIX are controllable by user settable parameters. These parameters are relevant to all versions of VIX, with the current status of each displayed on the help screen ('=' command). These paramaters are set using 'nq:p', where p is one of the following parameters.

nq:a - set autoindent. A value of 1 turns on autoindent, 0 off. When autoindent is on, each new line started while in insert mode will be indented to the same leading tab/blank space as the previous line. Use blanks or tabs to add indentation, and backspace to backup over indentation.

nq:c - set cut mode. When cut mode is enabled (1), killed lines are also saved in the save buffer. This works for individual kill commands, e.g. 'dd', 'dd', 'dd' will save only the line associated with the 3rd 'dd', while '3dd' will save 3 lines in the save buffer. With cut mode off, lines are not saved in the save buffer.

nq:d - set home "display" line to n. The display line is the line the cursor homes to after a '^L' verify command.

nq:e - Expand tab value. The default value for ':E' is 8, which causes the tab character (^I) to be expanded to multiples of 8 columns. Setting ':E' to 0 will cause tabs to be displayed as '^I' instead. Other values are possible, but less useful.

nq:f - Find case mode: n <= 0 sets find mode to search for exact case of pattern, n > 0 (default) set search mode to ignore upper/lower case.

nq:m - Match wild cards. (default=1). If on, then matching of the VIX wild card sets is enabled. If off, then the wild card control characters will match the actual control characters in the file.

q:o - set output file name. When ':o' is entered, you will be prompted for the name of the edited output file. This overrides the '-o' command line switch, and can be used to change your mind about the name of the edited file. If the output file name is different than the input file name, the input file will not be renamed to the backup file name.

nq:r - select repeat buffer n. (default=1). Repeat buffer n becomes the current repeat buffer executed with the '@' command. The '=' will display the current contents of repeat buffers.

nq:s - scroll lines: This parameter sets how many lines the cursor will move before the screen scrolls. 'q:S' sets how many lines cursor will move above and below home display line before scrolling.

nq:t - tty mode. A 0 is screen mode, a 1 is tty mode. (This command is useless on the Atari, but useful on slow mainframes.)

q:u - set User Wild Cards. After entering :U, you will be prompted for a user wild card set. You can use backspace to correct your entry, and '<Esc><Backspace>' to enter backspace and '<Esc><Esc>' to enter escape.

nq:v - virtual window lines. The 'n:V' will set the virtual window to n lines. N must be between 3 and the number of hardware lines on the terminal. This feature was desinged for busy time sharing systems and slow modems.

n:W - set auto wrap width. The ':W' parameter sets the column number used for auto wrap mode. When the auto wrap is set to a value greater that 1, VIX will automatically insert an end of line when the user types the first blank after the given column.

***** Word Processing Features

VIX has some limited word processing capability. This is the autowrap feature, settable both when you first run VIX, and by the ':w' parameter. Setting autowrap to column 65, for example, will tell VIX to automatically insert a newline whenever you enter text past that column.

The '!' tidy command is specifically designed to improve the appearance of strictly text files. The '!' tidy command will fill source text using the same right margin currently set for auto-wrap. Tidy performs essentially the same operation as a word processor fill function. Word are combined on one line until the auto-wrap

margin is passed. The 'n' count refers to the total number of resulting lines, not the number of original lines. Specifying a large 'n' will tidy large sections of a document. The tidy command recognizes lines beginning with blanks, tabs, or a period, and blank lines as special. It will not fill those lines, thus preserving paragraphs, tables and NROFF-like dot commands.

***** Other Features

For programmers, VIX has an autoindent command. The ':a' parameter controls this feature. When enabled, VIX will automatically match the leading white space at the beginning of the previous line.

The 'q(' command is used to toggle between line resolutions on the Atari ST monochrome monitor. Each 'q(' toggles between 25, 40 and 50 line resolution.

The 'qj' command will cause a "jump" back to the line of the previous cursor position. The major intent of 'qj' is to restore the cursor position if a large cursor movement command is accidentally entered (like when you thought you were in insert mode). It is also useful after using 'qb' to make a backup copy of the file. The sequence 'qb', 'qj' will write the file, then restore the cursor positon.

The 'nm' mark command notes the current line positon. Values of 1 to 9 are allowed for n. 'nM' restores the position. After entering '3m' for example, you can then move around the buffer, and later use '3M' to return to the marked location.

***** Startup and option switches

To edit a file using VIX, enter the following command line (if you have a shell - otherwise provide the parameters to the TTP box):

```
vix filename -switch1 -switch2 ...
```

VIX has several switches which control certain operating characteristics. Each switch begins with a minus (-), and is separated from the file name and other switches by a blank in the standard UNIX/C convention. Some switches may be negated by using a 'nox' form. Thus, '-b' will cause a .bak file to be generated, while a '-nob' causes the .bak file to be deleted on exit from the editor. This capability is indicated by []'s. As many switches as necessary or desired can be used at one time in any order. A ':' may be used instead of a '=' for '-c' and '-o'. The various switches supported include:

```
     -[no]b -- generate a .B[AK] version of the original (the usual
          default).  The -nob option means no .BAK file is generated.
          This latter mode of operation follows the normal Unix
          convention of not keeping past generations of a file.
     -[no]i -- auto indent mode enabled.
     -o=filename -- send edited output to filename.  The output file
          can also be changed at any time during the editing session
          with the ':o' command.
     -r -- read only - file can be read in only
     -s -- big save buffer - leaves more buffer for save file
     -w -- word processing mode - sets autowrap on, margin to 65.
     -# -- entering a number from 3 up to the number of lines on the
          screen will create a smaller VIX editing window.  This is
          most useful for slower baud rates.  A -7 makes a nice, small
          window showing 7 lines.

************************ COMMAND SUMMARY ***************************

     The available VIX commands are summarized below.  The first
column of each entry has a character noting similarities and
differences with the real vi commands in the following fashion:

- means present in vi, not implemented in vix.
= means commands work identically {with possible minor variations}
+ means new or significantly different command
* means "equivalent" command, somewhat different than vi
<space> means command unused in both vi and vix.

  n in front of command means command takes count argument
  [synonyms indicated in brackets]

   ^@: Unused
   ^A: Unused
= n^B: Backward window. {2 lines of continuity not preserved}
   ^C: Unused
= n^D: Down half window.
-  ^E: Not implemented
= n^F: Forward window.
*  ^G: memory status, short info line
= n^H: backspace Command mode: left; Insert mode: del last char
=  ^I: inserts tab in insert mode, not a command.
= n^J: down arrow in column [j,^N]
+ n^K: up in column [k,^P]
=  ^L: verify screen [^R,z]
= n^M: down to beginning of line [+]
= n^N: [j, ^J]
   ^O: Unused
= n^P: [k, ^K]
=  ^Q: Unused (flow control)
=  ^R: Redraw screen [^L,z]
=  ^S: Unused (flow control)
```

```
+  ^T: TVX prefix command - see q [q,Q,T]
* n^U: Up half window.  ** in insert mode, does NOT erase line **
*  ^V: Not a command.  NOT literal quote in insert mode.
*  ^W: Not a command.  NOT used for delete word in insert.
   ^X: Unused
-  ^Y: Not implemented
-  ^Z: Not implemented
=  Escape: forces command mode, safe follow char for d,c,q.
   ^: Unused
-  ^]: Not implemented
-  ^^: Not implemented
   ^_: Unused
=  <space>:  [r]
+  n!: Tidy.  Fills n lines up to wrap margin. [see autowrap]
-   ": Not implemented
+ n#p: execute repeat loop number 'p' 'n' times
=   $: goto end of current line {end is newline, not last char}
-   %: Not implemented
-   &: Not implemented
-   ': Not implemented
-   (: Not implemented
-   ): Not implemented
+   *: insert last matched pattern into text buffer
=  n+: [CR, ^M]
-   ,: Not implemented
*   -: Used in vix for negative counts, use K for up line.
-   .: Not implemented, repeat loops are a substitute
=   /: search {Escape used to end pattern, multi-line patterns ok}
*   0: 0 is used for counts (especially for : parameters)
= 0-9: count value for numeric arguments {may be negative!}
-   :: Not implemented - use ZZ and ZA to exit
-   ;: Not implemented
+  n<: Begin repeat loop. Loop terminated with >$$. ($ = Esc)
+   =: Help screens
+   >: Used to terminate repeat loops.
=   ?: Reverse search {search begins on previous line}
+  n@: execute current repeat loop n times (shorthand for n#p)
=   A: append to end of line
*  nB: back a word {vix's concept of words is different than vi}
=   C: changes rest of line
=   D: delete rest of the line
-   E: Not implemented
-   F: Not implemented
=  nG: goes to line number n, or end of buffer if no n supplied
*   H: Beginning of buffer (first line in buffer)
=   I: inserts at beginning of line
=   J: join lines {not needed since vix treats newlines as chars}
+  nK: Up a line to beginning of line
*   L: bottom line of file
+  nM: return to marked location n (n from 1 to 9, see m)
=   N: like n, but in reverse direction
=  nO: open a line above current line. n opens n blank lines.
=   P: put save buffer above current line {save buffers not named}
```

```
+   T: tvx commands (see q) [^T,q,Q]
*   U: very limited undo!! It only restores the LAST line killed!
    V: Unused
*  nW: Moves forward n words [w] {vix's concept of words not same}
=  nX: delete n characters before cursor
+  nY: append n lines to save buffer (see y), does not change buffer
=+ Zx: exit from vix (ZZ: normal, writes file, ZA: abort, no changes)
-  [[: Not implemented
    : Unused
-  ]]: Not implemented
=   ^: beginning of line {1st char of line, NOT 1st non-white char}
+   _: invoke indirect command file
=   a: append text starting after cursor
*   b: back up a word [see B]
=   c: change c, <sp>, ^, $, or / (delete, enter insert mode)
    =   c - change line
    =   <sp> - change one character
    =   ^ - to beginning of line
    =   $ - to end of line
    *   w - next word {VIX's concept of word different}
    -   b, and any others not mentioned not implemented
    +   / - the last thing found, yanked or put
=  nd: delete d, <sp>, ^, $, or /
    =   d - delete line
    =   <sp> - delete character
    =   ^ - to beginning of line
    =   $ - to end of line
    *   w - next word {VIX's concept of word different}
    -   b, and any others not mentioned not implemented
    +   / - the last thing found, yanked or put
-   e: Not implemented
-   f: Not implemented
    g: Unused
=  nh: Move left n characters [BS,^H] {will move over lines, too}
=  ni: insert (if value n supplied, then that ascii code inserted)
=  nj: down lines, in column [^J,^N]
=  nk: Up lines, in column [^K,^P]
=  nl: right n characters [<space>] {moves over lines, too}
*  nm: mark cur. line as location n.  Use M to return to location.
=   n: find next (in same direction as last ? or /)
=  no: open n following lines
=   p: put save buffer after cur line
+   q: Prefix character for "extended" commands
        b: goto real beginning of the file
        e: edit repeat buffer
        j: jump back to last location
        p: put external file from save buffer (writes file)
        r: restore repeat buffer
        s: print screen
        w: write buffer, read in next page of file being edited
       -n causes a buffer up to current line to be written
        y: yank external file to save buffer (reads file)
        /: cross buffer search (does automatic 'qw' on search)
```

```
     nq:p: set parameter 'p' to value 'n', parameters are:
         a: autoindent (1 means on, 0 off for all "switch" pars)
         c: "cut" mode (means 'dd' saves line in yank buffer, too)
         e: expand tabs to n spaces (8 default)
         d: home display line (where cursor homes after verify)
         f: find case mode (0 is case insensitive, 1 exact match)
         m: match wildcards (1 use ^A, ^L, etc., 0 no wild cards)
         o: requests new name for output file
         r: set current repeat buffer to n
         s: scroll window, cursor moves s lines before scrolling
         t: tty mode - 1: tty, 0: visual (you probably don' need this)
         u: requests entry of user wild card set
         v: virtual window size
         w: autowrap limit

=   r: replace next char with next character entered
=  ns: substitute: delete n characters, enter insert mode
-   t: Not implemented
-   u: Not implemented (see U)
    v: Unused
*  nw: advance word (see W)
=  nx: delete n characters
*  ny: yank text to save buffer - will save n lines into save buffer
       (Only one save buffer, 1st y clears buffer, rest add until
        non y command entered. dd works in a similar fashion, but
        kills as it saves (if cut_mode enabled)).
=   z: refresh screen (^L,^R)
-   {: Not implemented
-   |: Not implemented
=  n~: Change case of next n characters
* nDEL: Same as X, delete previous character

I had the same problem with uEmacs 3.7i that Phil Paone did (it
starts up and exits). Unlike Phil, though, I didn't have any
problems with the last version that came across the net.

Help... :-(

Summary:

As a followup to my previous article, I have come across a new encoding
technique (courtesy of the Math Faculty Computing Facility here at
the university) which has the following properties:

- eight bit input data
- very restricted character set
- generally compresses files rather than expanding them
  (including binaries)
- need no bit level twiddling
- involves only table lookup

The encoding system is easy to implement. I am whipping one up now.

This should make the transmittable archive format very easy to implement.
My co-developer, Mike Gore, is planning to do a Basic (gack spew) version
after I write one in C.

Still: comments?

>>>>> MMMUUUNNNCCCHHH!!! <<<<<<<

I'm not sure of which version of 1st Word people are calling the "updated" one. I just recently bought a 1040, and the version of 1st Word that came with it was 1.06. This version does not have any _DOCUMENTED_ multi-columnar format, nor does it fix that very anoying exit from the editor when a save is done. To answer the question about double spacing: on my version (1.06) you go to the Style menu and select the Spacing option. Note that this does not change an already existing document to be double spaced, one must Restyle the entire document first.

Hope this helps.

Any questions or comments or corrections should be e-mailed to me.

It is closest thing to the real thing on the ST. I can highly recommend it
after using it daily for almost a year.
Other products:
     Micro Rtx: a real time kernal, supports multiple procsses with round
robin preemptive priority based scheduling. Interprocess comm using mailboxes
(queus) and interprocess signalling.
     MT -Cshell: even closer to the real thing, uses Micro Rtx.
     Micro Tools : a collection of unix like utilities.
     Micro Make: what you'd expect.
     Hard Disk Accelarator: a write thru cache, handles multiple
partitions. Cache size is configurable.

Subject: GENLIB fix for reading standard input from the keyboard
Message-ID: <8610212152.AA29232@ucbvax.Berkeley.EDU>
Date: Tue, 21-Oct-86 23:20:33 EDT
Article-I.D.: ucbvax.8610212152.AA29232
Posted: Tue Oct 21 23:20:33 1986
Date-Received: Wed, 22-Oct-86 06:36:22 EDT
Sender: daemon@ucbvax.BERKELEY.EDU
Organization: The ARPA Internet
Lines: 174

This is a fix for gemlib distributed with the toolkit (not the latest version)
that has the problem of not correctly reading standard input from the keyboard.
I did some disassembling with SID and found a fix by changing the routines
read() and _pc_read() in gemlib. Read calls _rdasc() for ASCII files (CRLF->LF
conversion) and _rdbin() for binary files. _rdasc() and _rdbin() call
_pc_read() which (finally) calls the GEMDOS Fread routine.

I know the real fix is to throw all those CPM68K fileio routines out
and replace them completely, but this works for the time being.
It works correctly with and without standard input/output redirection (tested
with Beckemeyers Micro C-Shell, single user version).

Assemble pcrnew.s and rename the object file to pcr.o.
Compile readnew.c and rename the object file to read.o
Replace the modules read.o and pcr.o in gemlib with AR68 or with ARXX (an
AR68 replacement I wrote, which will be posted within the next few days).

```
-----------------cut here----------pcrnew.s---------------------------------
*    pcrnew.s  Together with readnew.c a fix for reading from stdin
*              in original Atari Toolkit gemlib
*
*    Author:  Ton van Overbeek
*         TPC862@ESTEC.BITNET

          .globl    __pc_read
          .globl    __pc_write
          .globl    lmul
          .globl    _trap

          .text

__pc_read:    link a6,#-2
```

```
        movem.l  d5-d7,-(a7)
        move.l   8(a6),a0 fd
        move.w   -$e(a0),-$2(a6)    GEMDOS handle
        move.l   $10(a6),(a7)  buffer
        move.w   $16(a6),a0    # of sectors
        move.l   a0,-(a7)
        move.w   $14(a6),a0    sectorsize
        move.l   a0,-(a7)
        jsr  lmul     # of sectors * sectorsize
        addq.l   #8,a7
        move.l   d0,d6         save count
        move.l   d0,-(a7) count
        move.w   -$2(a6),-(a7) handle
        move.w   #$3f,-(a7)    F_Read
        jsr  _trap
        addq.l   #8,a7

*   Now we test if we deal with stdin from the keyboard
*   This is so if 1. GEMDOS handle = 0
*                 2. F_Read didn't return with an error
*                 3. Handle 0 is not redirected (Tested by
*                    Fseek returning 0 if not redirected)
*              and  4. Read count is less than the max count

        tst.w    -2(a6)        filehandle = 0 ?
        bne  pcrend        no
        tst.l    d0        yes, GEMDOS error ?
        blt  pcrend        yes
        move.l   d0,d7         no, save read count in d7
        move.w   #$1,(a7)  handle 0 redirected ?
        clr.w    -(a7)
        clr.l    -(a7)
        move.w   #$42,-(a7)
        jsr  _trap
        addq.l   #$8,a7
        tst.l    d0        yes, if seek result > 0
        bne  restord0
        cmp.l    d7,d6         read count = max count ?
        beq  restord0 yes, no action

*   Now we are dealing with a read from the keyboard terminated
*   by CR. The CR is not put in the buffer by GEMDOS. Because
*   the C library wants LF, we add a LF to the buffer.
*   To stop the calling routine (__rdasc) from calling us again
*   we also put in ^Z to signal End-Of-File. This is corrected
*   in read again (See readnew.c)

        move.l   #LF,(a7)
        move.l   #$1,-(a7) 1 char to write
        move.w   #-$1,-(a7)    handle -1 is always screen
        move.w   #$40,-(a7)    F_Write
        jsr  _trap
        addq.l   #$8,a7
```

```
          move.l    d7,d0          restore count
          movea.l   $10(a6),a0     buffer
          adda.l    d0,a0          last char in buff + 1
          move.b    #$a,(a0)+ put in '\n'
          move.b    #$1a,(a0) and ^Z to stop __rdasc reading
          addq.l    #$2,d0         adjust # of chars in buffer

*** DON'T REPLACE THIS LINE WITH YOUR MESSAGE ***

Gold Star also made the old Tu-tone Monitors. The problem
with the new monitors is probably not that the suppliers are
using crummy parts, but that they are not correctly aligned.
It takes 1 Human 15 minutes per monitor to do the job right
at the factory. If you have a crummy monitor get it aligned
under warrenty. If the dealer refuses and says that there is
nothing wrong with it, then demmaned that he/she trade you
there old "Good" show room monitor for your crummy monitor.
If the service centers get flooded with requests for alignment
then Atari will yell at their suppliers to get the quality up.

                  ihnet!bryan

p.s. If the new monitors are crummy then Atari could be in trouble
for false advertising if its dealers use "old" monitors on the
display floor.

I, for one, am strongly opposed to trying to develop a new "standard"
decoding scheme. For one thing, it will be next to impossible to get
agreement from such a large group on what it should be. The effort will
cause more problems and confusion than we already have.

I have never experienced the problems with curly braces but it is possible
I suppose that we don't ever get messages that pass through EBCDIC machines
here. Certainly, I have never gotten any C source that had the curly braces
corrupted.

I have versions of uudecode in turbo pascal, c , and microsoft basic. This
is pretty wide availability and the basic while slow should be easily
adaptible to most machines. I don't think there will be too many problems
getting a version. Just ask in net.sources.wanted.

The problem with having to use the editor has nothing to do with uuencode/
uudecode. The problem is that some news software running on some machines on the
net
truncate files longer than 64K bytes. Unless the mail software is changed,
you will always need to get rid of the mail header/signature information
put in by mail as this is ascii too. You will probably have to do this
with an editor. I failed to find this task difficult.

I don't know about other sites, but 99% of the problems we have here are
files which are corrupted in transit, either because the sender posted
files larger than 64K and they got truncated or some of the information
was just corrupted in transit. A new scheme is not going to fix this.

I vote that we stick with uudecode/encode. If you have problems with these,
I am sure someone on the net will be glad to help you get them worked out.
I receive files all the time that have been arced and then uuencoded and
am able to reverse the process without problems.

[So you thought there were no bugs left, eh?]

Hi... uEmacs 3.7i works and is wonderful. But, as always, we unsatisfied users want more! Here are 5 bugs and 3 suggestions which I would appreciate your help with:

1. It looks like ^U (control-U) still isn't bindable in 3.7i. I can BIND-TO-KEY something to ^U, and DESCRIBE-KEY shows ^U as being bound to this new thing, but hitting ^U still does an ARG (i.e., I get 4 in the command line, then 16, etc.). I suspect ^U is hardwired into the code at the point where ARG is done, along with the ESC-number sequence.

2a. I'm not sure you'd agree this is a bug, but I think it is. When searching for something, hitting ^J, ^M or RETURN in the command line (in response to the STRING: prompt) all result in <NL> becoming part of the search string (even if I precede it with a ^Q). How, then, can I search for or replace a ^M or a ^J? (Some Kermits, for example, insert spurious ^M's at the end of each line, which one may want to replace.)

2b. Using ESC to delimit search strings is silly. If you really don't want to use RETURN, why not use ENTER? Better still, I would suggest using RETURN, and making ^J insert a ^J in the search string, and ^M a ^M. That way you can use ^J to get a NL in the search string (since ^J is a NL), and RETURN can still delimit the search string which is makes more sense since I think it's more intuitive. In fact, I usually use control-RETURN to delimit search strings since it is faster to type ^S-^RETURN when you want to repeat a search than ^S-RETURN (you don't have to lift your finger off the control key in the former). I would suggest using RETURN and ^RETURN to delimit search strings. If you have ^Q, you can always type ^Q-RETURN anyway to get a NL, though with ^M and ^J you really shouldn't need to. Hitting ESC to

delimit the string is inconvenient.

3. There should be a way to turn off the BIND-TO-KEY echoing when uEmacs reads in the EMACS.RC file.

4. Is there documentation available for 3.7i? I was thinking of the syntax of regular expressions in particular, but a brief description of each function and customizable flags would be nice too.

5. I can't bind ABORT-COMMAND to anything (say, ^G) in the EMACS.RC file. It doesn't bomb; it just doesn't do anything. But if I type BIND-TO-KEY ABORT-COMMAND ^G using ESC-X once I'm in Emacs, the binding does go through, even though the exact same line in EMACS.RC does nothing.

6. The SHELL COMMAND function restores HIREZ mode even if I start out in MEDREZ mode. uEmacs still thinks there are 24 lines, however, so I get a screen that's scrunched up towards the top. (What does the SHELL escape do anyway? What commands does it (and FILTER-REGION) recognize?)

7. uEmacs should provide command completion in the add/delete-mode commands. It's a pain to type out the name of the mode in full.

8. How do I get mouse movement to move my cursor? All I get when I move the mouse are various unbound-key or undefined-macro error messages.

In summary:

```
bug   -- 1.  ^U isn't bindable.
bug   -- 2a. Can't search for ^M and ^J.
sugg  -- 2b. Inconvenient and unnecessary to use ESC for delimiting strings.
sugg  -- 3.  Should be able to turn off BIND-TO-KEY echoing.
query -- 4.  Documentation?
bug   -- 5.  Can't bind ABORT-COMMAND.
bug   -- 6.  SHELL restores HIREZ.
sugg  -- 7.  Command completion for mode names.
bug   -- 8.  Mouse movement doesn't move cursor.
```

That's about all for now (I'm sure I'll think of more later!) Not to detract from your program though -- I think you guys have done an amazing job. 3.7i is definitely and by far the best editor I've used on *any* micro.

Cheers -- Ashwin.

I have now posted the Structured Programming Language to net.micro.pc. The reason it is there ONLY is because the article is in 5 parts and is very large. Installations with older software news programs make multiple copies of articles that are posted to more than one conference so I wanted to avoid extra wasted space on those machines. Those of you with atari ST,amiga,apple macintosh computers with hardware or software add ons that allow IBM or msdos compatibility, THIS language will run on your computer also. If you have any questions call me at 516 694 5872.

  I may have missed it, and if I have will someone please mail it to
me, but is there any documentation for UniTerm? I really like the
program, the zoom mode is very nice, but can I zoom back out? How
do I enter the VT100 setup modes? These are two questions I would really
liked answered (especially the zoom).
  Nice program Simon, could you give me a little help on the above
questions, I am sure others would also like to know. Thanks.

Alite does not work on monochrome systems (I should have stated this
fact when I posted the beast). If you have a color system, then be sure
to extract both 1alite.pic and 1alite.sng and store them on the same disk
as alite.prg.

Mark Williams C for the Atari ST - A Review

Mark Williams has released an EXCELLENT C for the ST. (C for the Atari ST, Version 1.1, Mark Williams, 1-800-MWC-1700, $180).

My first reaction upon receiving my compiler was a REAL C working environment at last! It comes with a shell program (the WEAKEST part of the package) that supports a unix like cc compile sequence. It has environment variables that tells cc where the various parts are (cpp, c0, libraries, etc.). It knows all about paths, and is EASY EASY EASY to use, unlike the developers C.

Included with the package are a large number of Unix-like utilities: ar-archiver/librarian; as-assembler; cat; cmp-compare files; crashdmp-atari crash analyzer; db-symbolic debugger (looks good, and has usable documentation, unlike sid in developer's); df-disk free space; diff; drtomw-convert dri to mw; egrep-pattern matcher, reasonably fast!; help-almost like man!; ls-lots of directory options; make; me-micro emacs; mf-free ram; nm-prints symbol tables; od-dump utility; pr-print; size-size of a file; sort; strip-remove debugger info from .prg files; tail.

The most sorely lacking utility is more. REALLY needed, but if you are fast with ^S.... Their shell is also not as good as you might hope for. The script language is a bit weak. For example, if you don't define one of the parameters ($1, $2, etc., just like Unix), it chokes. There are no if or shift operators to avoid the problem. The history mechanism is also crummy - it work realtive to the current command, so you do '!-3' to re-do the 3rd previous command. Who remembers what they did 3 commands ago, or wants to count lines. Oh well, I hear that Breckmeyer is supposedly working with Mark Williams to settle on a common environment organization, which is essential to smooth operation of cc.

Documentation is excellent, although it appears to be a bit behind of the actual code (I have C Version 1.1). A few missing options (which you see in the usual Unix "usage" fashion anyway), some missing error messages. The documentation is a thick (650+ pages), paper back book.

There is support for all the Atari libraries - VDI, GEM, TOS, ROM, AES. There is NO RCS support however, which may be a major problem for some developers. You could use the developer's RCS. There is no need to escape to assembly ever, as far as I can tell. There is full support for all the easy calls, as well as a nice LINE A interface - you can use LINE A directly from C. All of this is well documented, although the AES and VDI refer you to the Atari GEM

documentation.

This is REAL C, folks. No funny stuff. Most of your UNIX code can port directly with probably the only worry handling the CR/LF problem (which MWC does using "rb", "r+b", etc.). Pointers are 32 bit always. The compiler produces very helpful error messages, and detects some lint-like problems (variable unused, questionable pointer stuff, etc.). Library is richer than developer's C, better documented.

Mark Williams is even friendly on the phone. I called about an undocumented error message I got, and I got through to the technical staff right away (on the 800 number, no less), and they seemed knowledgeable and eager to help. (Try that with Microsoft!).

Too good to be true? Well, not so far. Finally, here are some numbers I gathered on MWC vs. Developer's C on two programs - the sieve benchmark, and my screen editor, TVX, which is several thousand lines long. Compile times are for an atari 20 Mb hard disk.

	program	Compile/link time	Code Size	Run Time
Developer's C	sieve	2:01	9225 Bytes	4.8 sec
Mark Williams C	sieve	:36	7366 Bytes	4.8 sec
Developer's	TVX	20:29	51517 Bytes	----
MWC	TVX	8:40	52472 Bytes

The best I have seen thus far is the public domain intersect ram disk.
It's an accessory that allows you to reconfigure on the fly. I would
be happy to give out copies, IF, I knew what uucoding was. I use it
primarily for two things: 1) copying files (natch!) 2) downloading
with PC Intercomm. I've found that I need it to access Compuserve at all.
The disk access gaps are too long and Xmodem overruns without the ramdisk.

                              John.

From the sounds of recent messages, I am not the only one who would rather be
using an Atari at work rather then an IBM. Whether a ST or a XE/XL is, I
think, a moot point. At work (Tektronix, Clark County) I have two options at
present: I can use a Tek 4107 terminal to a Gould 9000 mainframe, or I can use
an IBM-XT (576k) PC. What is so bloody frustrating about the IBM is that
everything that I can readily do at home on my 130XE takes a change in dip
switch here, a new ... board there, etc. My Atari's are set up for color, the
IBM requires a special color card; the Atari is set up for graphics, the IBM
requires a special graphics card! Who says that the IBM is better? Arghh!!
[The Gould 9000 is down so much as to become almost a non-option.]

I have finally found a good equivalent IBM program that is very similar to
Atariwriter or Atariwriter +. It is pfs:write. Similarly, pfs has equivalent
software to SynCalc, SynGraph, SynFile, etc. I suspect that AW is a clone of
pfs:write or that pfs:write is a clone of AW, and that both are also similar to
Applewriter.   pfs:write is probably not the most sophisticated wordprocessor

in the world, but it is simple (KISS) and works! I have about had it with "enhanced" programs that add more controls, commands, etc. then ten people could use or figure out.

Back to my original point, I just wish that Atari would become respectable enough to allow its use at "work"! Still am tempted someday to bring down a spare 1200XLE (256k upgrade) and use it for my wordprocessing!

--Bill--

==> I hope that the above will generate some discussion, particularly discussion of experiences with using non-IBM in work environments.

Not realizing that ARC would become a required utility for downloading future good stuff from the net (like UniTerm5c), I didn't save it when it was posted. Could some kind soul please email it to me, or possibly repost it if others are in a similar situation?
Thanks very much. C. MacCarley (maccarle@ed.ecn.purdue.edu)

Lines: 64

A week or so ago I posted a program to convert scribble formatted files to proff. Actually the native format is that used by Perfest Software's old Perfect Formatter program, but close enough. Since then I've made a number of improvements to it. The following commands have been added:

```
case:     Include a paragraph if a switch variable is defined.
device:   Choose one of the pre-defined printer types and use
          its escape codes to underline, bold and super/subscript.
note:     Make an endnote and place a note number in the text.
cite:     Make an MLA style endnote and turn on the bibliography
          functions.
```

Other functions that deal with variables and file inclusion have also been added. But I would like to say more about 'cite' and the bibliography functions.

Let us supposed that you have a source text file called CHAPTER1.MSS. In the same directory, you have an additional file called CHAPTER1.BIB. If CHAPTER1.BIB is an ASCII file of the following format:

```
~TYPE   :BOOK (OR JOURNAL, MAGAZINE, INBOOK)
@TAG    :UNIQUEWORD
@AUTHOR :Fred Jones (used for the endnote)
@BIB    :Jones, Fred (this is for the bibliography)
@TITLE  :The world is your oyster (except for the months with an R in them)
@PUBL   :Random House
@CITY   :New York
@DATE   :1985
@PAGE   :20-40 (ignored by cite but may be used by bibdump)
@MEMO   :(completely ignored, but can be used to write summaries)
` <-- that's the data terminator an accent grave.
```

And then suppose you've got 30 or so of these entries each of a similar format. The first time the program sees '@cite(UNIQUEWORD)' (UNIQUEWORD matches the tag field of an entry) . . . The first time @cite() comes along, the program reads the biblio file and installs the values into a structure for each tagged entry. From then on in the document any time it sees @cite(), it searches the structures (dynamically allocated doubly-linked circular list) for whatever tag is between the fences in the @cite() command. When it finds an entry, it creates an endnote for that entry, formatted according to the type. (i.e. if it's a book, the publisher and city are included. If the editor field or translator field is defined, then her name is

included). At the end of processing all of the tags are placed in a large array (allocated by malloc at runtime, based on the total number of entries actually in the bibliography file). The array is passed to qsort and then the sorted bibliography is dumped to the output file, again in MLA format. To change formats all you need to do is change the routines that write the notes and the bib. I think it's a handy little program, and if anyone is interested, I'm willing to mail source and docs in arc/shar format. I would send uuencoded binaries, but I can't find uuencode anywhere.

Finally, if you requested this software earlier, but haven't heard from me, please send another request. Our system has been having air conditioner problems lately and is in the habit of "forgetting" how to reply to mail. Even though we are a BITNET site, ARPA addresses seem to be accepted much easier by our mailer.

i quote the AT&T software announcement for C++ :

> "Given a running version of the C++ translator on a system
> mentioned above, it can be ported to a different type of
> system, if the target system has a C compiler that supports
> variable names of arbitrary length, and structure assignment."

The systems "mentioned above" are AT&T Sys V,Release 2.0 on VAX and 3Bx computers. i don't know what system calls are used by the C++ translator itself, so i don't know what mods might be needed for it to run under

BSD systems or v7-like systems (Alcyon C).

The porting procedure is related in the "Release Notes", part of the
C++ distribution.

Educational (source) licensing is $250 per *request*, no limit on # of
CPUs. Commercial (source) licensing is $2000 for the 1st CPU, $1000
for each additional CPU. Binary sublicensing is available for $2000
plus from $50 to $500 per copy sold.

Note that Oasys (Cambridge, MA) also sells C++. Their phone # is
(617) 491-4180. i don't know any particulars about their product,
since i am still waiting for their info to arrive in the mail.

~~~~~~

Unfortunately it is largely hypothetical. There are two points of concensus in this discussion. 1) We all want C++ for the ST, and 2) Nobody knows whether it exists.

> Where can I get a copy of C++ (or cfront, or whatever) ? Does C++ also
> exist for the Vax ?
>

Cfront (the C++ "preprocesor") exists for BSD UNIX running on VAXen. (and, I suspect, any other BSD4.2 installation)

i saw a whole flock of requests for Xinu go by on unix-sources/net.sources a while back, but nobody bothered to say just what it was. What is the book to which you refer? Please also give us a high-points description of Xinu and maybe some comparisons to other common OSs, so that we might dispense with the book if it's really ugly.

Excuse me if I'm the 1,000,000th person to ask this. What is uucoding?
Are there any sources or conversion tables? I have a bunch of stuff I
would like to share with the net, plus, I can place this stuff in the
BCS (Boston Computer Society) Public Domain Library. Thanks.

In the May '86 issue of BYTE, Webster shows benchmarks comparing the Mac, Amiga, and ST. The disk i/o results look like this:

	Mac Plus	ST	Amiga
Write	2.3 (sec)	30.3	7.3
Read (seq)	1.1	15.9	5.1
Read (random)	4.6	14.2	17.8

Is this possible? How can the ST disk i/o be so much worse than the other two and what is the explantion?

On UniTerm 1.5c and bombs:

We have tried to run uniterm (hardware: 520st+, 1meg, 20MB harddisk)
with GDOS loaded at boot time --> bombs. Then we cancelled GDOS,
and voila, it works fine.

On uniterm: the best terminal emulator i have seen till now. Great Job, Simon.

>
>>Also, it was my understanding that this new release of 1st Word would
>>allow for 2 column output, and the insertion of Degas-format images.
>
I was working on the PCW show on the ATARI stand (helping out) and for one
day was demonstrating 1st word plus, so lets try and help.

1) 1st word plus is a new product, not a new release, and costs about
   90 pounds.
2) i believe the final version will have multi column output, but the press
   release version ddid not, so i dont know for sure
3) it can import graphics, in a special format. (low, medium, or high)
   (if you use the wp in the wrong res the picture is shown on the screen
   as a black rectangle) - the pictures can overlap each other, and the text.
   they provide a snapshot accessory (ie cant be got at in degas or neo)
   which can snap a portion of the screen in there own compact format,
   degas format, doodle format, or neo format - therefore you would need
   to convert degas or neo images to, say, doodle format so that you could
   snap them with the desk accessory.

>I have a few other questions about 1st Word as well:
>
>1) Does the new version have ways to make big moves around the screen
>without using the mouse? In specific does it have an easy beginning of
>line or end of line command (like emacs Ctrl-e)?

4) big moves work as before, by mouse

>2) Is there any way to drive the more "exotic":-) printers like my
>NEC 8023? (A general OS print driver (accessory ?) would be nice so that
>screen dumps to non-Epson printers would turn out)

5) printer driver is altered as before, except there are a few extra options
   to support graphics and rulers (rulers allow blocks of text to be in
   pica, elite, condensed, and expanded elite.

>3) Is hyphenation supported?

6) yes, when it needs to hyphenate a word (if hyph is enabled) then it shows
   you how its going to do it, and allows you to alter the hyphenation position
   if you want to.

>4) Are some of the annoying things about the old vesion corrected like
>
>   a.Outputting a blank page on printing
>   b.Exiting the edit file on save (I guess
>   I'm in the habit of frequently saving)

7) a) yes, infact you can sor that out in version 1.6 of 1st word (update
   free) aswell)
   b) yes, there is a save and resume option.

>For now, 1st Word fills most of my word processing needs but in the future
>I may be needing a more complete (spell checking, hyphenation, footnoting,
>etc) WP. What other WPs are available and what will they offer.

8) it includes a built in spellchecker, with a 40000 word dictionary (if
   i remember the size correctly) - you dont need to drop out of wp to
   check spelling or alter the dictionary.

9) footnoting has also been included.

10) dont know much about any other wps, I like 1st word+

The following causes my recently purchased Megamax C to crash:

```
struct i {
     unsigned short j;
};
main(){}
```

Remove the unsigned or the short and everything is hunky-dory. Can
anyone else verify this problem? Please mail directly to me rather
than to the net and I'll post a summary if appropriate.

Nonetheless, I recommend Megamax C and its documentation very highly.

While I'm at it - the Beckenmeyer Micro C Shell ($50) is hot stuff
as well. People who are used to BSD unix will find it a familiar
and rich environment - history substitution, aliases, smart shell
scripts, and a lot more. Micro Tools, at $24, is well worth it.

If anyone has a working copy of Uniterm and Gem-Kermit
preferably with docs, (and is willing) I would like to send you a
disk with return postage to get a copy of these two great PD
programs. I have a modem on order, and will need some software
with download capability (hopefully kermit) to take advantage of all
the stuff floating around on the net.

Just send me your name and address if you are willing to do this
for me.

I'm having problems with MandlBox. The program appears to load and
starts to run alright. I can play with the pull-down menus, and draw
a box in the coloured window (it's always orange), but as soon as I
let it start calculating, the screen goes blank, then approx. 15 secs
later, I get a small block of the window that is under the arrow,
two bombs appear and I'm back to the Desktop. (2 bombs --> bus error)

Is it my machine?? 520 with ROM TOS + 1 Meg.?? Its hard to beleive
that a program could be corrupted so that it almost runs...

In my opinion the book is nothing short of excellent! It was the
first OS text I read that allowed me to associate well known
abstractions with very clean, readable, high level, REAL code. I liked
Comer's writing style - fast reading (well organized and succinct),
lots of information.

The book...

Summary: Any ideas on efficient coding of B&W line drawings?

[]

I've been thinking recently about transferring ST screen-dumps (32K
bit-maps, one bit deep in "hires" (monochrome) mode) over the modem
(to a VAX running UNIX, to print the graphics on a laser-printer).

Since my applications are concerned with B&W line drawings which are
mostly white space, it would be very inefficient to send the whole
32K. Also I'd like some compression method to compress it before I
ever save it on the ST disk.

I guess I could use ARC or some other standard, general purpose
compression program. But it seems that an algorithm designed
especially for this purpose should beat general ones handily!
I am thinking about an algorithm that would compare bytes (or words)
VERTICALLY DOWN THE SCREEN, rather than along consecutive RAM.
Such an algorithm would find more runs of identical bytes. It should
also work for color.

Is such a thing available (preferably PD)? Is anybody working on one?
Or should I do it myself?

Summary: MWC good for "developers", not "personal" use!

[]

From what I've heard, Mark Williams C is great. The remaining
problems are supposed to be solved in the next release.

BUT: (THE CATCH!!!) You HAVE to have a hard disk to make any
serious use of it!!! It is FAR too slow on floppies (to my taste).
(And you HAVE to have TWO DOUBLE-SIDED floppies if you want to go
that way...) It is too slow on a hard disk, too!

So in my opinion Megamax is still the only viable option for
"personal" (low-budget) use, and is superior to MWC in speed
of compilation which is important to all users.

Consider: Megamax is so compact I put the compiler, linker, libraries,
microEMACS, utilities (from micro-C-Shell) in a (576K) RAM disk,
and still have some 250K free RAM disk space left! In the rest of my
1040's RAM I have micro-C-Shell resident, and enough space to run
all those things one at a time. Compiling and linking (all the way to a
.prg file) a small (2-page) program takes about 15 seconds, all done in RAM.
(MWC on a hard disk is an order of magnitude slower.) I can
put the source for microEMACS (180K) on the RAM disk, and compile
it completely in RAM!

Now if only somebody would figure out how to make Megamax and I/O redirection
from within Micro-C-Shell work together...

What is commercial in posting an update of existing software? Do you want to
take money for this driver? If so, than you're right, it's commercial.

>> About a year ago I was flamed very much by members of Atari (US) and other

>eventual decision to make the CP/M emulator available as a free program was
>based on the fact that everyone had it already anyway! A big manual and
>support will not be available, sorry, but we just can't afford it.

May I remember you, that we were explicit allowed by Atari Germany to post
that CP/M emulator to USENET. Only two weeks after my posting, a new
release of the emulator was published here in Germany. In the meantime
there are n+1 new releases of the emulator (many corrected bugs, works
with ROM-TOS and so on). I have not posted even one of this new releases.

With the hard disk the current emulator still doesn't work. So I would say
IT IS STILL IN A NON-SELLABLE PRODUCT. And so the emulator is still
PD in Germany. But the newest news, a final version is on the schedule,
it will also support the hard disk and this product WILL BE SOLD (no PD)
here in Germany. And final, if we hadn't posted the emulator, you could be
shure any other her in Germany had done it. Today in the age of international
computer networks you cannot make a program PD in one country and sell it
in another country.

i don't object to volumes of crap (thats what usenet is all about)
what i don object to is the cost of the volumes of crap
the "three people asked for it so here it is all 2,500 machines" syndrome
do any of you guys have ANY idea what this costs the 95% percent of usenet
who are not interested?
[as an aside i should point out that i am interested in the 520 et al -
i'm just concerned about people mentality when it comes to glibly spending
hundreds of other people hard earned dollars/pounds/dmarks/franks/etc]

Both Megamax and Lattice treat unsigned as a type rather than a type modifier. I think your problem is stemming from this (yet another custom interpertation of C) assumption.

GDOS will be available to users (as opposed to developers) once a few more fonts are completed. Then it will be packaged and sold to everyone.

We have several old color monitors, several new color monitors and several
Ps 3000 (color with floppy drive built in). After reading your article
i went and took a closer look at them. Frankly, i find NO big difference.
I suspect that you have gotten a piece that is slightly misaligned or
something.

Tracy, I followed your idea of last posting to do strange things with
restricted character sets, and I think I have found a nice way to do encoding/
decoding without too much overhead. I'll send you the sources if you want.

Encoding scheme:

     Assumptions:

          The character set contains the digits 0-9,
          and at LEAST the letters A-P.

The letters A-P are the Hex values 0-15. Two hex "digits" are always together. So AA is 0, and PP is 255 (standard hex, with different characters). The digits 0-9 are used as a decimal repeat count. The count is 1 less than the number of characters to repeat. This implies that a repeat count of 1 is interpreted as "two of the following"(obviously no repeatcount implies that there is only one of the following).

Caching is implemented by using other characters (except whitespace) as "cache" values of the most frequently used values. This requires a two-pass encoding scheme, but a one pass decoder.

The encoded file has a series of lines at the head seperated from the body of the encoded test by a blank line. This is the only whitespace dependency. Each line in the head contains three characters (plus the newline):
a character for the cached representation, and a two hex digit code that the cache character represents. Since the caches can be anything besize 0-9,A-P and whitespace, that leaves a lot of choices. Plus it can even be dynamic. No caching leads right to a hex encoder(with its two for one expansion), but with caching characters enabled, the size of the encoded output is smaller.

An example of encoding:

The line:

This is a test of the emergency broadcasting system <52 characters>

Becomes:

<blank line>
FEGIGJHDCAGJHDCAGBCAHEGFHDHECAGPGGCAHEGIGF
CAGFGNGFHCGHGFGOGDHJCAGCHCGPGBGEGDGBHDHEGJ
GOGHCAHDHJHDHEGFGNAK   <108 characters>

Which is like BinHex(in a way), but if I use the letters
Q-Z as caching values, the file changes to:

QCA   <Q is caching the hex value CA>
UGB   <U is caching the hex value GB>
WGD   < Etc... >
RGF
XGH
YGI
VGJ
ZGN
SHD
THE

FEYVSQVSQUQTRSTQGPGGQTYRQRZRHCXRGOWHJQGCHC
GPUGEWUSTVGOXQSHJSTRZAK

Which is the same size (108 characters) But since the input is short,

it does not give the caching a chance to be effective.

I'll compare my encoding scheme to uuencode and report on the results.
On to gigantic programs, and since its for binary, I used my Sun 3.0
Kernel as the acid test:

```
-rwxr-xr-x  1 root       493853 Apr  8  1986 /pub/vmunix
     <plain>
-rw-r--r--  1 barada     680443 Oct 24 14:05 vmunix.uuencoded
     <uuencode>
-rw-r--r--  1 barada     670910 Oct 24 14:07 vmunix.encoded
     <encoded>
     Note, The cache values used were Q-Z and a-z (36 cache values)
-rw-r--r--  1 barada     600208 Oct 24 14:31 vmunix.encoded
     <encoded>
     Note, The cach values used were  Q-Za-Z and:
          !@#$%^&*()-_+=|{[}]:;<>,./       (62 cache values)
```

As can be seen, my encoding scheme can produce a smaller output that
uuencode, but I don't have any checksums in my scheme.

Compressing the above encodings produce the following results:

```
-rw-r--r--  1 barada     387571 Oct 24 14:05 vmunix.uuencoded.Z
-rw-r--r--  1 barada     346875 Oct 24 14:07 vmunix.encoded.Z
```

So my encoding scheme expands a binary file by 35.85% compared to
uuencodes 37.78% which isn't much different.

What is really useful is the ability to limit the caching values to only
those that can pass through the networks, and to be almost completely
whitespace independant. It also doesn't perform so bad either.

Any comments or ideas???

Thanks, I knew it was something silly like that. Option no. 1 didn't seem
to work, but no. 2 works just dandy. I'll post the source to the net once
i've commented it a wee bit.

Let's start with the bugs. First, the easy one:-

```
   while (!(isalpha(f1 = getchar()))) ;
```

where f1 is a char variable, fails to compile under megamax. Agreed, I should probably use ~ rather than !, but it is OK on other compilers.

Mention of ~ reminds me that when I sent over my programs via kermit from this 4.2bsd vax the various ^L put in to force a newline on the listings got translated to something which megamax did not like, but which printed as ~ on the ST. I thus deleted the various ~ by hand (on my C64 I have a program to do it!), including some ~ which were meant to be there! Can megamax have an equivalent/identical character, or at least ignore whatever ^L becomes?

Now the main course, which has caused much gnashing of teeth and wails from the family (are you STILL on that bloody computer?). My favourite program (a chess problem solver) works on several machines, but not (yet) on the ST. One of the reasons is shown by the following program.

```
#include <stdio.h>

typedef         char    unsn7;          /* 0 to 127        */
typedef         char    void;           /* no return()     */

typedef         unsn7   piecear[65];
typedef         piecear piecemv[8];
typedef         piecear *piecept;

     piecemv king;
     piecept mset[8];

void    main(argc,argv)

     unsigned argc;
     char    **argv;
```

```
{
     unsn7   mysqr;
     unsn7   dir;
     piecept piecemat;
     unsn7   *pieceset;

 mysqr = 15;
 dir = 0;
 king[dir][mysqr] = 24;
 mset[5] = king;
 piecemat = mset[5];
 pieceset = piecemat[dir];

 printf("\npieceset[%2d]=%2d piecemat[%1d][%2d]=%2d king[%1d][%2d]=%2d",
 mysqr,pieceset[mysqr],dir,mysqr,piecemat[dir][mysqr],
 dir,mysqr,king[dir][mysqr]);
```

gives the following output

```
pieceset[15]=24 piecemat[0][15]= 1 king[0][15]=24
```

Having disassembled, the reason is essentially that the code takes piecemat to be the matrix itself, rather than a pointer to it. The disassembled code for piecemat[dir][mysqr] is

```
     move.b  -1(a6),d0       mysqr into d0
     move.b  -2(a6),d1       dir into d1
     ext     d1              extend d1 to 16 bits
     muls    $65,d1          65*dir in d1
!!!     lea     -6(a6),a0       address of piecemat
     add.l   a0,d1           add 65*dir to d1
     ext     d0              extend d0
     move.l  d1,a0           shift d1 to a0
     adda    d0,a0           add mysqr to a0
     move.b  (a0),d0         the (false) value
```

There are many ways round this, of which one is to change the typedef for unsn7 to int (yes, this is better anyway, but on 8-bit computers like the C64 I gain a lot with using char). The code then is correct

```
     move    -2(a6),d0
     move    -4(a6),d1
     muls    $130,d1
     add.l   -8(a6),d1       using the content of piecemat == -8(a6)
     asl.l   $1,d0
     move.l  d1,a0
     adda    d0,a0           now a0 really has the right address.
```

I am pretty sure that there are other bugs to do with use of char
for small integers, but I don't have the courage to look for them:
I have simply changed to int. Incidentally, the definition of void
as a typedef is necessary: what a pain.

Next problem: my program sometimes goes into suspended animation
(loops somewhere), sometimes mushrooms and sometimes shoots back to
the desktop. When it loops then I know where it has got to according
to the output, but I hoped that the recently-distributed watcher
program might get me out: it has no effect. Does it work for anyone?

For the cases where the program mushrooms or returns to the desktop
I would like to see what was printed right up to the fatal instant, by
forcing standard output onto my printer. The manual talks about
redirecting output, but I cannot find a way of doing this by a >?
parameter to a .ttp program. Anyone done it? Of course, I can send it
to a file, but if the program loops the file is never closed, so stays
empty. Also, of course, file output is buffered, so that I miss the
end part.

Another minor grouse is that of missing library routines. I needed
bcopy, bcmp and ffs (even the C64 has these). Of course I can easily
hack them, but has anyone started a supplementary library?

Yet another problem concerns dynamic allocation. I need to build up
linked structures (not big, but lots of them), so I use malloc and
free. The manual talks about malloc getting 8 kB chunks, but does
not explain if these are automatically split for many smaller mallocs.
I thought that I could see by printing out a pointer in %x8 format.
However, what is printed is only 16 bits (try printing king[0] and
king[1] in the above program!). Is there a way?
Also, should I try Malloc (possibly increasing the heap size)?

Final question (are you asleep yet?): can I link from a RAM disk
(containing megamax folder but not the source/object files)?
If yes, does it need the RAM disk specified in the list of object
files. Which reminds me that the program is split into about a dozen
modules, which is too many to link by using the shell and pointing
to the files one by one, or even listing them in a link program
call. It would have saved me some time if the manual had told me that.
(the above means can I do the library search, of course).

Just as a point of interest, this program always gives problems when
moving to a new compiler. That is because I use it to teach myself
about C constructs. If I were trying to write a portable C program I
should be much more careful about writing "simple" C.

Mike Gerard

** Oh No! It's the line ea

Hi. This will be a many faceted posting so get ready to skip parts:

1) Does anybody have either C code or uuencoded binary of the uuencode/uudecode programs that were posted on the net a little while ago? If so, write me mail please. It'd be nice to have them on my Atari and I don't have a Pascal compiler.

2) I'm thinking of buying a (much needed) hard disk and I am soliciting any reviews/comments in email about them. Are the Atari and Supra the only two out there? Do either of them have an automatic (on power-down) head park?

3) Anything on DRI multitasking GEM?

4) I just acquired Silent Service by MicroProse. Let me say that this is an interesting game that is halfway between an arcade game and a strategy game. Realistsic movement and control, and intelligently planned graphics make it a fun diversion. Submarines have never been so fun. A neat feature is the time scale setter. If you think the games is going too slow, set the time scale to be 2, 4, or 8 times normal. The only major problem is . . .

FLAME ON ->
I really hate it when companies protect their software, and then charge money for backup disks. I have already paid for the program, and if I am being legal, and not copy-breaking it, I don't want to pay $10 more for a backup disk for when (in this case) the original disk starts making funny noises when the drive is running.
FLAME OFF ->

I realize the utility of copy protection (being a writer myself), but occasions like this are frustrating. Maybe there is some better way . . .

5) The clock setting program I got from the net didn't work (bombed

out). Is there anybody nearby that can send me one?

6) Kudos to the authors of Uniterm and Arc. They are great and useful programs. Long live the Public Domain and the authors that support it!!

That's it folks. Poke the guy next to you if he's fallen asleep . . :-).

The problem is square brackets, which do not exist in EBCDIC in any
standard form. This becomes a real pain even with source programs

written in C and Pascal.

Come on! Thats an AWFULLY BIG statement!
I agree that the PC has a LOT of public domain software (quantity) but I
bet it would STILL lose to CP/M in the quantity department. CP/M was
developed and nutured on PD stuff.
I certainly don't agree that it beats the MacIntosh in the quality
department. I will admit that this has a lot to do with the Mac user
interface. But in both commercial and public domain software, I would say
that the Mac has the PC beat hands down. (Especially in terms of USEABILTY).

>]]

This is another BIG statement. I always love hearing from PC users bragging about there 16 bit machines. It remains a fact that ALL software designed for the PC is designed to be able to run on the original PC using the 8088. It is also a fact that INTEL(!) describes the 8088 as an 8(!!) bit processor with some 16 bit facilities. Even the Z80 (8 bit and proud) can do 16 bit math. - No I'm not an 8 bit user (anymore. I have a 1040ST), but I refuse to be blind to 8 bit processors

Keywords: Lattice libraries

Upon reading the code for the shar/unshar program recently posted to the net, I noticed the warnings about the Lattice C libraries. Since Lattice has released version 3.03.04 (the comments apply to version 3.03.02), I felt I had better post a copy of a letter I sent to Lattice regarding problems in the newer library. The 20 file problem has been fixed, but some other problems have been introduced that will affect compiling shar.

Sept. 13, 1986

METACOMCO
5353E Scotts Valley Drive
Scotts Valley, CA 95066

Dear Sirs:

I have your Lattice C compiler, version 3.03.04, serial number xxxx for the Atari 520ST and have some comments on the product. First, the bugs.

Try running the following program (enclosed is the output).

```
/*This program tests a bug in the Lattice compiler, version 3.03.04*/
#define SIZE 12
main()
{
        char db[SIZE], *tmp;
        int r1, r2, r3, r4, zero=0;
        tmp=db+SIZE-1;
        r1=db-tmp;
        r2=tmp-db;
        r3=db-tmp+zero;
        r4=tmp-db+zero;
        printf(" db-tmp=%x tmp-db=%x\n db-tmp+0=%x tmp-db+0=%x\n",
                r1,r2,r3,r4);
        r1=0+db-tmp;
        r2=0+tmp-db;
        printf(" 0+db-tmp=%x 0+tmp-db=%x\n", r1, r2);
}
```

Here is the output:

```
 db-tmp=0 tmp-db=FFF09042
 db-tmp+0=F6FBE tmp-db+0=B
 0+db-tmp=F6FBE 0+tmp-db=FFF09042
```

I find the results to be somewhat inconsistent and confusing, even for C! It looks like there is a serious problem with pointer arithmetic.

Try to write anything to stderr (printf(stderr,...). or puts(stderr,..), or even write(2,...)). The cursor drops down a couple lines and everything stops. I found touching control C at least got me out of the program. Version 3.03.02 did not have this problem.

I opened an ASCII text file for level 1 input (open() and read()) and read it in. I got EOF before the file had been completely read. Setting ORAW in the open mode cleared things up.

In the area of clarification, I think there are a few things that must be made explicit in your manual:

> I/O redirection on a program's command line must be done before any commands to the program (close examination of

your manual shows this, but many people familiar with systems like UNIX(tm), don't have that restriction).

> redirects stdout and < redirects stdin (see page 14)

There can be no spaces between the redirection symbol and the file name.

When compiling a program that uses AES and VDI calls through the Lattice library, do not use the -n option (31 character symbol names), because the library only has 8 chararacter symbols; thus, the entries won't be found.

Finally, a couple of questions. How do you pass definitions to a compile? The -D option can set flags for #ifdef and #ifndef, but the compiler chokes on parsing -dsymbol=value. Last, but not least, when is the next improved version due?

- -

The important point is that shar writes to stderr. I found that changing the fprintf(stderr,...) calls to cprintf(...) and fputs(...,stderr) to cputs(...) solved things.

One last question for anyone on the net. I heard at a users group meeting that a patch exists for the Lattice library that permits I/O redirection under the Beckemeyer Micro C-Shell. Does anyone have that patch and if so, could I get a copy?

I would suggest that you get your monitor or console repaired. I have one
of the new monitors and they don't look bad. It looks a lot better than
IBM's monitors. From the symptoms that you describe, it sure sounds like
the monitor or the console blanking is either missing or weak.

I've heard alot of talk for the past months about the mysterious
Atari Explorer magazine. I've been on the look-out for it at the
bookstore, but never saw it. Well, it's finally out.
The Sept/Oct issue I have is 80 pages of software/hardware/program reviews
and news for the ST. Atari, it was a long wait, but it looks like it was
worth it.

Now, I have a question: Does anybody know anything about a mag called
STart. I saw an issue, I don't know how old, in my bookstores junk box,

evidently there because of, as the note on top said, 'fault disk'. So,
I assume that STart includes an ST disk with each issue, full of interesting
things. Anyone know what I'm talking about (I sure don't :-)).

                                Maurice T. Franklin

You have two choices here: one buy the new XEP80 80 column adapter device or
two, buy software that allows 80/132 wide screens (with horizontal scrolling).
Admittedly horizontal scrolling is the pits but it beats 80 columns interlaced
into 38 columns.

While I was no getting into modems, I will admit that you need an 850 interface for almost anything, be it modem or printer. (Or another 850 equivalent--except that Atari is providing an RS232 port on the new XEP80 for printer or whatever. And trying to find cables to connect a IBM into anything as simple as a Epson printer can be just as much a pain. I have an easier time locating Atari cables then IBM cables unless I go to mailorder.

> piracy.
I think that there is as much public domain software out there for the Atari 8 bitter as there is for IBM. And the software that you buy at the dealer (read: commercial software) is a heck of a lot cheaper for Atari then IBM. Although they are getting closer! Atariwriter+ costs $49.95, pfs:write costs $89.99.
> There's a guy who gets pissed when, for example, Analog states
> that there isn't much Atari software because of piracy, but who has a
I agree that piracy is deplorable, but I doubt that anyone does not have some pirated software. My feeling is that if it is still available at the dealer, then you should pay for it. (Dealer being anything from your local computer store, to mailorder, to the publisher of the software). But, and this is a big but, if it no longer is available anywhere legitimately, then I will used a socalled "pirated" copy. This generally applies to games, as they seem to be the most pirated software. I don't think that I have ever seen real useful software pirated (ala Syncalc, SynFile, etc.), these are currently available and are reasonably priced so there is no incentive to pirate them. Or am I being undully naive?
>
>   However, after all that, I'd much rather have an ST on my desk. It

> than the 8-bit line.
I am glad that you like the ST line, personally I hate mice and windows with a passion. But admittedly the ST line is fairly well thought out line. It should get more software as time goes on. And you have to admit that the 1200XL was an aberrition. I have two of them as well as my 800XL and my 130XE. So I have had experience with them -- I have never had any software that I could not use on all four machines, albeit some on the 800XL requires the translator disk and more on the 1200XL require it. Apparenly the 130XE OS has been corrected as it seems to take software that the XL's require the translator for. Two of the machines (800XL and one of the 1200XL s) have had the Newell 256k upgrades installed. For all practical purposes, they are the equivalent of the 130XE now, except that they still sometimes require the translator disk. Example: the new Atari Planetarium program (which I recently

purchased) will load up on all of the machines. The 1200XLE requires the translator, the 800XLE does not. However, during the time that the program is calculating, the 130XE shows the correct screen , the XLE's show gibberish. Apparently the Planetarium program uses a different form of bank selection or something.

At anyrate, getting back to my original discussion: I have purchased AW+, SynCalc, SynFile, SynGraph, etc. and they would suit my "business" needs just as well as the software I have at work for my IBM-XT. Maybe I don't have quite the memory available, but it is adequate for what I need. There is even a form of CAD available now for the XE (albeit somewhat crude). So I say that the XL/XE series are just as useful in business as the ST (unless you really need the .5 -- 1 Meg of memory). [And the 130XE can be pumped up to 1 MEG if you need it!]

Not snobbery, but your only advantage is memory and possible IBM compatibility.

Having never used C or Pascal or Action! I cannot testify to the usefulness of the 8bitter machines, but these languages are available for the XL/XE's.

Warning. Beckemeyer MT C-Shell will NOT work with Lattice C. Execution of
      Lattice-C binaries will cause a panic and the ST will lock up,
      requiring reboot. I have talked with Beckemeyer about this and they
      recognize the incompatibility and are working with Metacomco to
      resolve the problem.

I have also experience problems with PC/InterComm from Mark of the Unicorn.
This involves loss of the curser when I return to the shell. A few times I
have gotten ASSERT errors and a stack trace. I am still trying to rediscover
what I did so I can forward the information back to Beckemeyer.

Beside these two difficulties, the MT C-Shell seems to be a reasonable
environment for ST programmers who come from a UNIX background and want
something familiar. I have found only a few annoyances and differences
(for example ^Z/carriage return for eof instead of ^D).

STart, the ST Quarterly, is a new quarterly magazine about the ST (and future high-end Atari computers ...) published by Antic Publishing. The first two issues, Summer and Fall 1986, have been out and available for some time; the third is scheduled for early December publication. The magazine costs $14.95 per copy, including a disk of all source code, executable programs, and datafiles required for the articles. No program listings appear in the text of the magazine -- all are given on the disk.

The magazine is highly recommended, but don't just believe a Contributing Editor :-) Go to B. Dalton, Waldenbooks, or any other vendor and decide for yourself!

After sifting through the mail, two thoughts came to mind:

First, I think an enhancement to uucoding is warranted. A simple checksum at the end would do the trick, and would be compatible with earlier versions. An earlier version would simply ignore the checksum at the end, with no further complications. It would a least help to zero in on network problems. As it is, most versions I have seen add a character at the end of the lines so that spaces are not truncated. Why not replace this with a simple checksum?

Second, the ST is an excellent work machine. The 68000 blows away the 8086 types. The lack of software, as has been pointed out, is only because the machine is only one year old. I held out until the ST came out, I have one of the first machines. I have done all sorts of work with it (at home, where I can find peace and quiet) from editing to graphics for presentations. I am completely satisfied with the performance. I have had absolutely no problems of any kind using the ST. I will admit that I am still awaiting a good symbolic debugger, perhaps Mark Williams is what I am looking for (You really need a hard drive to use it).

I am writing this article from an ST right now, using PC Intercom through an Avatex modem, as reliably as if I were in front of my VT100. As far as software piracy goes, people with money to burn on outdated PC's probably have money to burn on useless software. Anything super-expensive belongs on a mainframe anyways. Here is a list on things I want to be able to do on my ST, all which I am completely satisfied with:

Word processing
Telecommunications
Graphic illustrations
Games
Programming languages (with the exception of the symbolic debugger)
Spreadsheet analysis

All this stuff is available. Now. I'm not looking for a turn-key system

to run my business for me. (which is a dangerous prospect, to say the least, refer to the court case against lotus)

Anything a manager has against the ST in favor of the PC is purely ignorant bias. He most certainly has been watching too many TV commercials.

John.

Keywords: Epson MX100 screen dumps

HELP PLEASE!!

I just bought an Atari 1040 ST and hooked up my ancient
Epson MX100. Everything works fine on it (1st Word, print
files) but when I press ALT-HELP to dump the screen, I get
strange results. It prints the graphics ok, but for each
line of graphics it also prints 3 blank lines in between.
Can somebody give me a clue as to what I need to do. I've
configured the "install printer" accessory correctly (not
much choice in that) and I've set the dipswitch 2-3 to "on"
instead of off. The switches were the same as from factory
otherwise but that still doesn't help. And as some may know,
the manual for this printer is far from good.

Can anyone help me. How about Neil? How about Epson? Are you
listening/watching?

Thanks in advance,

Alan Davis

If you have upgraded to a better system, and have an old 1541 disk drive
lying around (or if you know of someone who does), I would like to buy
the drive from you.

If the drive has been serviced to permanently avoid the famous
"head knock disalignment" problem, all the better.

The cable and power cord are essential, I need them both.

I will pay shipping - reply with your selling price either by email, or

>
Depends on what you mean by slow. Mark Williams C is about two and a half
time faster than Alcyon C. While not nearly as fast as Megamax C, at least
it doesn't resrict you to 32k code segments!

You DO NOT have to have two double-sided floppies. Mark Williams has
released a version that runs on two single-sided floppies. And if you have
a 1040ST or a 520ST w/ 1 meg, you only need one drive (either single-sided
or double sided) to use the compiler. To do this, you put the compiler disk
in the floppy and put your source code on a ramdisk along with whatever
other programs you want that will fit.

>So in my opinion Megamax is still the only viable option for
>"personal" (low-budget) use, and is superior to MWC in speed
>of compilation which is important to all users.

>
Speaking of low-budget use, Mark Williams C lists for $20 less than Megamax C. And Mark Williams Company gives dealers a larger margin on their product than Megamax; I bought Mark Williams C for $130 (list=$180) whereas I have yet to see Megamax for less than $190 (list=$199).

>Consider: Megamax is so compact I put the compiler, linker, libraries,

>- Moshe Braner

Nice, but with Mark Williams C you get a powerful Make utility, a small but useful shell program, and an assortment of unix-like utilities to round off the package into a powerful full-featured development system.

I'm not disputing that the Megamax C compiler is a good compiler, but I do disagree with Moshe's conclusion that Mark Williams C is only good for developers. If compiling speed isn't the only consideration you buy a C compiler for, then I would highly recommend Mark Williams C compiler.

I finally got the one meg upgrade to my 520 working, or so I thought for about an hour. When I tried to rebuild it into the case I had trouble booting. The drive failed to recognize that it hed a disk and just clunked at me every few seconds. This problem was at first intermittent happening about every other time I tried to use he drive but has since become perpetual. I have chked for shorts and can see noe and had the same experience with the dealer's functional drive. Could someone send me a few suggestions? Please write directly to my electronic address as I am no longer on the distribution list. Thank you very much.

Help!

I'm trying to compile bammi's MAKE on the new Alcyon (developer's) C compiler, but apparently don't have enough memory. Here's the error message:
  make: not enough memory for macro.

  It's happening on one of the macros defined by Make itself, so even if I don't define any macros myself, Make won't run. I'm a Modula2 user, and thus have very little experience with Alcyon C. Can someone tell me what to do? Is there a modification I can make in GEMSTART.S, or do I need to free up some memory... Any advice (no matter how basic) will be appreciated...

I have the C - source for a compression algorithm that reduces files to

about 20-30% of their original size. It uses the LZW algorithm (if you know what that is - I don't). It would be great to compress your files, but you might want to uuencode them before transmitting them. The only problem is that I don't have a C-compiler yet. If anyone is interested, I could get it to work on Unix 4.3 and then someone could translate it to the ST. You would need to keep the uncompress algorithm on your host system anyway.

Keywords: ST to 800xl communications using joystick ports

********** EAT ME **********

Hi,

I remember seeing an article awhile back about using the joystick ports
on the ST and an 8-bit for some kind of interfacing. I wasn't interested
at the time, but suddenly I want to use my 8-bit for SOMETHING again
(other than as a paper-weight) and I haven't got the article. Does anyone
out there have it, or does anyone know how to do this? Advance thanks,
-Leo

BTW, my memory is finally working and MAN am I glad I didn't buy an IBM
clone or a macintosh.... 8^)

Both Sundog (Software Heaven Inc, aka FTL) and Rogue (Epyx) are copy protected.
Worse, though, both insist on being run with the disks write-enabled.
This is a real ***** .

FTL, at least, tell you in the instructions that this is the case,
and offer an address from which one can (for $10) buy a single backup

copy. Epyx do neither.

I had a go at copying the Epyx disk. It appears to work, but when you try to run the copy, you get put into what appears to be an infinite 'put disk A into drive A; put disk B into drive A' loop. I actually gave that a try for a bit over 80 swaps, figuring that, since they hadn't said it was copy-protected, they might have simply made it 'unattractive' to copy by requiring that you somehow 'validate' the 80 tracks individually. Finally decided that's not the case. It annoyed me enough to decide that I think I'll try to crack that one, though.

Before I get flamed in turn, let me make it clear that I have bought, from authorised dealers, still shrink-wrapped copies of both at the proper price for real money; and that I want backups for my own use -- since I'm not convinced that I can run a write-enabled disk indefinitely without managing to have an accident with it.

I have a version of uue/decode that I have been testing and that seems to avoid some of the problems with the present setup. I added some code to the original programs to do some error checking. The format of the files the encoder uses is similar to the current version. If you have the current version, you can delete the extra information with your word processor. My version adds the following things:

1. It breaks up long files so that each uuencoded file is no more than 300 lines long.

2. It places and include directive at the end of each file at the break so the companion program can reassemble the files into a program.

3. It adds a key table at the beginning of each file so that

the decoder can index into this table to find the value for letters in the file. I discovered that the errors I had with uudecode were often because a mailer had changed each instance of a character to something else. This solves that problem.

4. It checks the key table for integrity before it decodes the file. This way if both 'H' and 'Z' have been changed to ' ', it will exit and tell you.

5. If it finds a letter in the file that was not in the key table, it issues a warning telling what the character was, the filename, and the current file position.

6. It appends a 'part' letter (a-z) at the end of each output line to avoid truncation problems.

This program makes uue/decoding somewhat simpler than it has been because it breaks the files up into parts automatically and reassembles them. It actually is smaller and runs faster than the net version of the program because I used freopen() to cut down on file pointers and I used register variables where possible. If you are interested in this program, drop me a line and I will post it to you.

Summary: a short program that seems to work

[]

Finally, it seems I am on the right track towards writing a program
that will stop other programs. The following, after running, sits
in RAM invisibly, until you hold down Control, Alternate and BOTH
shift keys and press another key (e.g. Return). The program in
progress at the time will be terminated.

One problem I had to solve was how to avoid OS calls from
inside the interrupt handler. I did that by using direct
peeking of the shift keys status, and by doing the actual
termination of the program AFTER the RTE.

WARNING: This program uses some addresses that are essential
but not official. I found them out by snooping around in the
ROM code. They may be changed in future versions of TOS.
Atari will send their death squads after you if you use these
addresses in a commercial program!

Here is the heart of the routine, in commented assembly syntax:

```
asm {
/*
 * call supexec() to install our thing
 */
    PEA  install(PC)
    MOVE.W   #38,-(A7)
    TRAP #14
    ADDQ.L   #6,A7
/*
 * terminate and stay resident
 */
    CLR.W    -(A7)
    MOVE.L   #0x00000200,-(A7)
    MOVE.W   #0x31,-(A7)
    TRAP #1
install:
/*
 * install our keyboard interrupt handler
 * (has to be done in supervisor mode)
 */
    PEA  handler(PC)
    MOVE.L   (A7)+,0x118   /* pointer to kbd intrpt subr */
    RTS
handler:
/*
 * check keyboard shift status
```

```
 */
    CMPI.B   #0x0F,0xE1B   /* shift status variable */
    BCS.S    normal
/*
 * overwrite return address with our posthandler
 */
    PEA  killer(PC)
    MOVE.L   (A7),6(A7)
    ADDQ.L   #4,A7
normal:
/*
 * go do the usual thing, usually return to interrupted program
 */
    JMP  0xFC281C /* where $118 pointed to */
killer:
/*
 * RTE to here to terminate program
 */
    CLR.L    -(A7)
    TRAP #1
/*
 * should not come back, but: 6 bombs if you do
 */
    CHK  #-1,D0
}
```

Here is a hex dump of the complete program (140 bytes):

```
60 1A 00 00 00 70 00 00 00 00 00 00 00 00 00 00
00 00 00 00 00 00 00 00 00 00 FF FF 2A 4F 2A 6D
00 04 20 2D 00 0C D0 AD 00 14 D0 AD 00 1C D0 BC
00 00 01 00 2F 00 2F 0D 3F 00 3F 3C 00 4A 4E 41
DF FC 00 00 00 0C 48 7A 00 1A 4E 71 3F 3C 00 26
4E 4E 5C 8F 42 67 2F 3C 00 00 02 00 3F 3C 00 31
4E 41 48 7A 00 08 21 DF 01 18 4E 75 0C 38 00 0F
0E 1B 65 0A 48 7A 00 0E 2F 57 00 06 58 8F 4E F9
00 FC 28 1C 42 A7 4E 41 41 BC FF FF
```

Please try it out and comment on its performance under various circumstances. Remember: the object is a clean break, with no after effects, avoiding RESETs when possible.

I've finally figured out how to get most of the special characters in the
1ST Word font table printed out by a Panasonic 1091 printer.

First, turn off the printer. Remove the clear plastic cover above the
dip switches. Flip dip switch #2 to the off position. Replace the cover.

Then install the pana1091.hex printer driver. I'll post this next.

Now you should be able to print out just about every character in the font
table (no Hebrew).

Hope this is useful,

Eric Bergman-Terrell

ok, how bout a compromise, if a command.tos exists it is executed,
otherwise the command (request) is ignored ????

*** REPLACE THIS LINE WITH YOUR MESSAGE ***
..... It supports both b/w and color monitors by
adding three new modes for the four screen resolutions as follows:

```
mode monitor type  screen resolution  colors
------   ------------ ----------------- ----------------
HIREZ    black & white 40 lines x 80 cols none
MEDREZ   black & white 25 lines x 80 cols none
MEDREZ   color         25 lines x 80 cols black,red,green,yellow
                                          ^^^^^^^^^^^^^^^^^^^^^

LOREZ    color         25 lines x 40 cols black,red,green,yellow,
                           blue,magenta,cyan,white
```

modes may be set by the sequence ^xm (cntrl-x m) and typing the mode as
shown. If a color is not one of the valid colors for that rez, then
the command is ignored, plz don't flame me yet, dan and i are
working on a method to change the pallette in a machine independant
manner

Here are some opinions about the problem of posting binaries, along with a draft solution. There should be some discussion on the net before it gets implemented.

Sources are no substitute for binaries, since not everyone has the same compiler, or even language, on micros.

Binaries have to be encoded as ASCII files. But there is no reason why we have to use uuencode! There are evidently problems with it, and we should feel free to invent an alternate encoding method which avoids the problems with uuencode. These problems, aside from the minor one that uuencode is designed for th Unix environment, are that some characters (such as curly braces {}) do not make it through all nodes unscathed (IBM machines and others with EBCDIC codes appear to be the culprits), and for long files the posting have to be combined in an editor. Another problem is that udecode is a complicated program which a lot of users have trouble getting or rewriting.

I propose that we develop an encoding method for microcomputers that meets these requirements:

> So simple that users can easily learn the protocol and write their own version of the decoding program. Uudecode is relatively easy to write in C, but gets tricky in languages that do not have low-level bit operations.

> Moderately compact, to keep the traffic volume down.

> Reasonably good error trapping to check for damaged files.

> Convenient to use, preferably not requiring the use of an editor even for multi-part postings.

One possibility would be to post hex files, but these are very bulky, at least twice as long as the binary being posted. However, a generalization of posting hex will work -- if we encounter the letter G in a hex file we know it is an error, but we can also adopt the convention that the letters G-Z do not have to be encoded, so that they are represented by one byte in the encoded file instead of two. This can save a lot of space. Based on this, here is my proposal:

*** TO ENCODE A FILE ***

Read through the file a byte at a time, and classify each byte as follows:

>OK, pass through unchanged

>TRANSFORM to a single byte

>ENCODE as a pair of bytes

The encoding I propose is a modified hex, using the letters A-P instead of the usual hex 0-9A-F -- the reason for this is that it is trivial to map this way, e.g., value = char - 'A'. The rest of upper case letters, Q-Z, can be used for error checking and for 1-byte transformations of common non-graphic bytes, such as NULL and NEWLINE. Thus the actual encoding rules could be:

>OK includes digits 0-9, lower case alphabet, and punctuation marks.

>TRANSFORM \0 -> Q, \r -> R, space -> S, \t -> T, etc.

>ENCODE all upper case letters and other characters into modified hex codes, AA to PP.

I have done this encoding on a number of files using a crude set of programs that I wrote a while back when I didn't have xmodem working on my net machine and couldn't get uudecode working on my micro -- the files were generally no larger than uuencoded files, often smaller.

To avoid very long lines, adopt the convention that white space is ignored, so that you can put in newlines wherever you want (probably not in the middle of a hex pair though).

To decode a file, one simply reverses the process. Read through the file a byte at a time, and use switch or a set of ifs to do the following:

>letter A-P? Read next byte and output 16*(first-'A') + (second - 'A')

>letter Q-Z? Output \0, \r, etc., according to above table.

>anything else? Output it as stands.

*** REFINEMENTS ***

I haven't said anything yet about error checking, convenience, etc. Note that there are several byte combinations that are not used in this scheme of things, specifically a letter A-P followed by Q-Z. These can be used to add these features. For example, an encoded file should begin with the pair AZ and end with PZ, similar to the begin and end lines used by uuencode. However, we could also adopt the convention that when a file is broken into parts, the first part ends with BZ, the next begins with CZ, and so on. This way one could simply decode a set of files without first combining them -- the program would start at the AZ flag, and stop when it found BZ. Then it would go on to the next file and search for CZ, etc. If it didn't find PZ at the end of the last file, or if the codes were out of order, it would complain.

Further refinements would be to add various checksums, set off by other unused code pairs. I'll pass on this one, since it sounds like a good idea, but adds to the complication. Perhaps it could be made optional, such as writing a checksum after each termination code like BZ ... PZ.

If this idea seems reasonable, perhaps net moderators could carry the ball from here. Unfortunately this site is not very reliable for news and mail.

Summary: Another failure

     The recent posting of Uniterm 1.5C didn't make it to our site. ARC unpacked the 1st file but choked on the .PRG file. I don't know for sur at this point what went wrong but I expect it was a truncated message.

Cheers! -- Jim O.

I'd like to know if someone on a Bitnet-Site has successfuly used ALITE.
The ARC-Utility claims all files (1alite.sng,1alite.pic,alite.prg) beeing
OK. Klicking ALITE.PRG --> the ST is rebooting.

Any hints ? This programs seems verry nice.

The new Version UNITERM 1.5c works very fine after downloading,
uudecoding and finaly ARCed. It's getting my favorite terminal
emulator.

A tip for OSS Personal Pascal users who swear by Emacs like I do -- if you
copy uEMACS.TTP onto a disk with the Pascal system and rename it to

EDITOR.PRG, Pascal will quite happily invoke Emacs when you edit a file, and
uEmacs will quite happily return you to the Pascal desktop when you quit.

My current communications program, with which I am generally pleased, is
Flash. I haven't yet uudecoded Uniterm or examined its docs. Can anyone
explain why one might prefer to use Uniterm over Flash?

Thanks,

I recently came across the address info-atari16. Not knowing exactly what
it is, I assume that it's a bulletin board for ST users. Is this the case?
If so, can I get on the mailing list or access the information by some other
means? In contrast to the Bay Area, the ST seems be be a rare beast in our
part of the world, and it would be useful to have people to communicate with.

Thanks,
              Roger Marks

Ok, on some machine somewhere the line-eater still survives. UNITERM
arrived here with a truncated part 2 and 3(three) different part 3s.
Fess up, who has been harboring and feeding the line-eater.
Could some kind soul re-post or e-mail parts 2 & 3(A &B) of UNITERM?

Summary:

It's all very nice that Uniterm is so wonderful, and that Arc is easy to use, but I haven't been able to get any Uniterm working yet. The latest release arrived here with Part 2 (UNITERM.A) truncated. I ran arc anyway, and it told me that a header was bad, and then it got a bus error. Not terribly impressive. I had hoped it could get one file out.

Could someone please repost or send me a copy of Uniterm Part 2?

Does arc really calculate a CRC on the members in the archive? I was planning to write a network transfer archive program (with no compression) which would:

- encode into a very (very!) restricted character set
- be much more efficient than uuencode for ascii text
- be as efficient for arbitrary 8 bit wide data
- perform proper CRC checking
- automagically split the archive into chunks for posting
- automagically assemble chunks from raw mail and news
- be fairly immune to added control characters (CR, LF, etc)
- be able to extract undamaged files from a damaged archive

This program could be used for transmitting anything. It would even be useful for text, as it would offer assurance of correctness, and would be cheap as transmitting text raw.

Any point it this? I already have the encoding part written for another project and the CRC stuff I stole, so it's not a huge amount of work. Arc's biggest problem is that you have to uuencode it, and uuencode is not robust (read: sucks the big one). If you think I should do this, let me know, and I will. It won't be a large program.

I've found several problems with uudecode, which are caused by
the uuencoded file being munged by 'terminal handlers' enroute to me.
The symptoms sound like some I've seen complained about, specifically
that the file appears to decode, but bombs. On looking at the files,
I found 2 different sorts of problem.

First, spurious 'control chars' get inserted in some cases. In fact,
these appear to always be NULs (0x0) put in as 'delay padding' by
someones term handling software.

Second, trailing spaces get stripped.

It is fairly trivial to modify uudecode to ignore all control chars
(less that ASCII space) -- and harmless, as they should not be in
a uuencoded file. Then, pad the line out to an arbitrarily large length
using spaces (I simply tack 64 spaces on the end, in my buffer, before
decoding a line). Appending 64 spaces is crude and inelegant, I know, but
it insures that there will be enough in all circumstances, and is a much
simpler mod than actually looking to see how many are needed -- especially
since the line may contain as yet unprocessed control chars to be thrown away.

Since making these trivial changes I've had no problems with uudecoded fils.

Hope this helps someone...

Summary: Improved version

[]

Recently I posted here a program that, after running it once,
was supposed to kill any program in progress upon pressing
Ctrl-Alternate-both_Shifts-Return. Turns out that the program
did not work outside of micro-C-Shell, and poorly even there!

I took a careful look at WATCHER.S (also posted here recently) and
noticed there that a kill is NOT done if the interrupted program
was in supervisor mode. I don't know why, maybe because that
signals that another interrupt handler (or TRAP!) is in progress.
Incorporating that idea, jumping to the last part of the ROM
bomb handler to do the termination, and some streamlining yielded
the following program which seems to work a lot better.
(you have to press Ctrl-Alt-both_Shifts-Return several times
sometimes, probably in order to catch it in user mode...)

Mystery remaining:

When it terminates, two bombs are displayed. WHY?

WARNING:

This program uses some addresses that are essential
but not official. I found them out by snooping around in the
ROM code. They may be changed in future versions of TOS.
Atari will send their death squads after you if you use these
addresses in a commercial program!

Here is the heart of the routine, in commented assembly syntax:

```
asm {
/*
 * call supexec() to install our thing
 */
    PEA  install(PC)
    MOVE.W   #38,-(A7)
    TRAP #14
    ADDQ.L   #6,A7
/*
 * terminate and stay resident
 */
    CLR.W    -(A7)
    MOVE.L   #0x00000200,-(A7)
    MOVE.W   #0x31,-(A7)
    TRAP #1
install:
/*
 * install our keyboard interrupt handler
 * (has to be done in supervisor mode)
 */
    PEA  handler(PC)
    MOVE.L   (A7)+,0x118   /* pointer to kbd intrpt subr */
    RTS
handler:
/*
 * check mode of interrupted program and keyboard shift status
 */
    BTST #5,(A7)       /* check for super mode */
    BNE.S    normal
    CMPI.B   #0x0F,0xE1B   /* kbd state variable */
    BCS.S    normal
/*
 * overwrite return address with fatal address
 */
    MOVE.L   #0xFC0A5A,2(A7)    /* near end of _term */
normal:
/*
```

```
 * go do the usual thing, usually return to interrupted program
 */
     JMP  0xFC281C  /* where $118 pointed to */
}
```

Here is a hex dump of the complete program (92 bytes):

```
~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~
60 1A 00 00 00 70 00 00 00 00 00 00 00 00 00
00 00 00 00 00 00 00 00 00 00 FF FF 48 7A 00 18

I've just gotten K-Resource, a resource construction set put out by Kuma (for lack of cooperation by Atari UK when I enquired about the developer's kit some months ago -- note, Atari, don't try to sell me one now, I've already spent the 400 quid on substitutes).

As an RCS, it looks fine (though they could do with hiring a
tech writer, a tech editor, and a photo-composition expert for their
docs). However all it makes is the completed resource 'object',
and the header (C .h) file (in a choice of 4 languages, of which
C is all I recall, cause it's all that interests me).

This would seem to rule out my use of RCSFIX technology, as you
don't get a 'source' for the .rsc file. Anyone out there have a
tool that will convert a .rsc 'object' file into a C source file
for same? Or a description of the .rsc structure in terms that
I could use to make a C-source generator with?

   (Replies to address in header, or to:

Was there anything worth mentioning at the Atari Expo at Portland OR
October 11-12, 1986? What is the status of the custom graphics chip,
2080ST and 68020? What specifically does the graphics chip do? Any
ROM port modifications? Any information is appreciated.

Curt

Sounds like sloppy journalism to me. To paraphrase a famous American author.
'Rumors of Amiga's death are greatly exagerated.' :^} I suggest that item 9
be changed to:

     9) Personal Computing Magazine. (Midnight Enquirer Award)

I'm tempted to buy the magazine just so I can get the address to write
the author a letter. Personal computer mags are (with a few notable
execptions such as DDJ) garbage. I definately would not trust some
bozo like this author to tell me which computer to buy. If I did I would
have an IBM PC/XT/AT compatable in front of me. After all that's what
everybody else has.

                        Mickey Mick Mick,
                        At your ....

     Every word of this is my personal opinion and does not reflect
     the views of my employer.

re: numbers of ST's
I just heard that in their prospectus Atari had to state how many
ST's they've ACTUALLY sold worldwide. I haven't actually read it myself,
but was told that the number in the prospectus was 125,000.

*** REPLACE THIS LINE WITH YOUR MESSAGE ***

i have a copy of xinu for 68000, but before anyone requests it be
sure that you know what you are getting (e.g. read the book!) xinu

is not a general purpose os like unix and (here i go shooting my big
mouth off) is really best suited for 'stand-alone' applications. OTH
i could be very wrong

    I looked at this article and saw an awful lot of IBM biases myself
along with ALOT of inconsistancies between their figures. Look at the
one place where they have the best selling software part and compare
its figures with the figures under the subcategories "Best selling
DBM", etc. I think its funny that they can have totally different
figures for the same package, in the same year, from the same survey.
I would really like to see reprinted in full the survey that they took
their figures from.

Well, folks, I just picked up a brand-new SC1224 color monitor, to supplement
my trusty monochrome. Now, one thing we all know is that the quality of
Atari's color monitor is excellent, right? Wrong-o. The quality of Atari's
color monitor WAS excellent. The old, Panasonic-supplied monitor had
fantastic quality. The new, Goldstar-supplied monitor is, to put it quite
bluntly, the pits. The video quality is a disaster. In medium-res, it
doesn't even look like the monitor is CAPABLE of handling the resolution.
Individual pixels are blurred, and the medium resolution display, in general,
looks like low-res looks on a TV set. It looks even worse than an Amiga in
80-column mode, if such a thing is possible.

I've always thought that one of the Atari ST's chief advantages over other

computers was the great video it produces. No more. This monitor is barely capable of handling 320x200, let alone 640. Atari has made a major, major mistake in switching suppliers. They are being penny wise and pound foolish, because this WILL hurt sales. The computer looks a lot worse on the Goldstar monitor. If I were shopping for a new computer, I sure would not buy one with such lousy video quality. Thank heavens for my SM124.

eat eat eat eat eat eat eat eat eat eat eat eat eat eat eat eat eat eat eat

I found my troubles in being not able to run some uuencoded programs
comming over the net.

The translation of the not-Char/circumflex(^)-Char is not unique.

Translating it to EBCDIC 5Fhex and sending it over some gateways,
it not always returns as EBCDIC 5Fhex, sometimes it returns
as EBCDIC 71hex. (I saw it sending it to ucbvax and return)
Now I have told our translation table to recognize 71hex as 5Fhex too.

Strange !

Maybe that this is a hint for those having no success in uudecoding.

I am looking for a ramdisk and would like some recomendations.

If you could mail (or post) info, I would be very happy.

Name,
Source of it,
cost, (or in Public Domain)
flexibility
    specify drive letter? without byte-editing the disk?
    specify size of ramdisk?
    can dynamically change its size?
any other features, like ease of use?
reliability,
documentation,etc.

Also, if you have a little one which I could create (through
BASIC file writes, etc .... I don't yet have a modem)
maybe you could send that also.

Also, know about any disk viewer/editors?

Thanks a bunch!

Is there really a C++ preprocessor available in the Public domain or has
this whole discussion re: long identifiers just been hypothetical.
Where can I get a copy of C++ (or cfront, or whatever) ? Does C++ also
exist for the Vax ?

A few remarks to some problems with my recent posting:
         - KeyEdit.Prg: the numeric keypad and the cursor keys in UniTerm are
                        'hardwired'..that means you can't change the meaning
                         of these keys except in keypad numeric mode! This is
                         not my fault, this is the way a VT100 works!!!!
                         The keypad has following modes:
                            VT100 numeric keypad
                            VT100 application keypad
                            VT52 numeric keypad
                            VT52 application keypad
                         The cursor keys:

VT100 cursor mode
VT100 cursor application mode
VT52 cursor mode

The strings sent are predefined and not user changeable!

-Kermit: I've tried UniTerm with GEM-Kermit and have had no problems with sending, receiveing and server mode (BTW a particular good combination seems to be UniTerm, Kermit and K-Switch which I was able to borrow for a few days). If anybody has had problems pls mail them to me (I consider this important!).

-Truncated postings: please don't post to the whole net! If you are on arpanet or bitnet mail to me and I will send you the missing parts a.s.a.p. (the only problem is that this is slowly turning in to a full time job (without any pay)). If you are on an other network pls give me a full description of network and node, I will the mail you a test msg.

Here a utility I made to use in the AUTO folder on boot disks without the Micro C-Shell or similar. It copies a number of files from e.g. floppy to ramdisk. It is not the utmost of sophistication (no wildcarding), but it works.
Enjoy.
----------cut here-----autocopy.doc----------
PROGRAM
   AUTOCOPY - Auto program to copy files at system boot

```
FUNCTION
   This program is to be placed in the \AUTO folder on the boot disk.
   It can be used to copy your favourite files to a ramdisk (which of
   course must exist before this program is run).
   It looks for the file \AUTO\AUTOCOPY.DAT which describes the files
   to be copied. The format of a line in AUTOCOPY.DAT is:

      <source file>  <destination file>

   An example :

      a:\xemacs.tos   d:\xemacs.tos
      a:\make.prg     d:\make.prg
      a:\gemstart.o   d:\gemstart.o
      a:\osbind.o     d:\osbind.o
      a:\gemlib       d:\gemlib
      a:\aesbind      d:\aesbind
      a:\vdibind      d:\vdibind
      a:\libf         d:\libf

CAVEATS
   Source and destination files must be specified with full path names
   in AUTOCOPY.DAT. No wildcards allowed.
   AUTOCOPY will not overwrite existing files (no extra copy at reset
   when files are still in the ramdisk).
   Linelength in AUTOCOPY.DAT is limited to 80 characters, so no very
   long path names.
----------------cut here-----end of autocopy.doc------------------------------

And now the program written with Alcyon C. Link with gemstart.o, osbind.o and
gemlib.

----------------cut here-----autocopy.c---------------------------------------
/*

This problem could be due to a loose keyboard connector.
Open up your ST and push the keyboard connector down so that it is
firmly connected.

     Rich and James,

I volunteered about two months ago. I even have a batch of votes that I posted
to this group and net.news.group. But with the impending reorg, it
was decided to postpone the creation until the reorg was in effect.

Once that is done, I'll start up the group.

Summary: Final version (hopefully)

[]

Reminder: after running this program ONCE, holding down
Control, Alternate and BOTH Shift keys and pressing any
other key will stop the program running at the time, as long
as it is in user mode. Since programs call OS routines
which execute in supervisor mode, and since this program will
act only if the interrupted program is in user mode, you may
have to repeat pressing the last key several times.

The two bombs were due to the RTE to $FC0A5A in user mode,
where a MOVE.L #$93A,$4A2 is attempted. Here is a corrected
version with BSET #5,(A7) added before the RTE, to keep it
in supervisor mode.

(Hex dump of the complete program - 96 bytes):
```

>but was told that the number in the prospectus was 125,000.

I have read the prospectus, and I believe the number given was about
150,000 , which rather made me a bit upset -- I have been suggesting
the investment to others on the basis of 250,000 sold. Is the diff-
erence do to an inflated "rumor" rate, or old data? I go the feeling
that some of the data in the prospectus was rather old. Just a hunch
though....   Neil?

This is my first posting.

I recently picked up a program that formats floppies with an extra 50 k per side. This is probably old news but if it isn't and you let me know then I'll attempt to post it.

I am going to be writting a desk accessory that will act as a normal address book with a few plus. I hope to post it when I'm done. If there exists any suggestions please mail them to me.

After I uudecoded UNITERM, I got UNITERM.ARC. Now what do I have to do to get
Uniterm.prg? Any suggestion is welcome and thanks in advance.

The ARC file unpacked fine, and the program booted on my b&w monitor.
Unfortunately, no matter what I clicked to be the proper buffer size,
I then got two cherry bombs (bus error).

I have interfaced the CDC drives that are sold by BG micro and those drives
(Full height DSDD) require at least 10ms step rate. Let the buyer beware!
Until someone come up with a 10ms step rate program, Those drives are
useless on the ST.

Summary: Time for net.sources.atari16?

It's beginning to look like it might be time to get
a net.sources.atari16. There are already net.sources.mac
and net.sources.amiga, along with some general 'C' type
source groups.

We might also be able to get a "bin" group as well?

Our "peculiar" format, unlike binhex or S-record formats
can be decoded on either the Unix host or an ST. Sources
have been posted for BASIC, C, Pascal, and Modula 2
versions. One of them seems to be incompatible with
the Unix version.

There are also versions of uuencode and uudecode available
for VMS, IBM PC's, and Amiga's. In other words, unpacking
should not be too difficult.

One concern is the net.sources.XX vs. the net.XX.sources
issue. Many S.A.'s do not want people putting net.sources
files in their personal accounts, but don't mind them transferring
files to their micro. The typical method of stopping access
is to make the directory (net/sources) executable and readable
only by the owning demeon. This effectively shuts of access
to all sources.

On the flip side, many sites archive net.sources.* to tape,
which makes this alternative attractive to sites with no
sources restrictions.

Since the newer news programs link rather than send multiple
copies, it might not be a bad idea to have both groups with
implied or explicit cross-posting.

One possible solution is to change net.sources to net.sources.general
and/or some further specific groups, so that there is no net.sources
group.

Feel free to forward this suggestion to any appropriate group.

Rex B.

Filtering long identifiers into short (but not mnemonic) forms would work, I guess. But since we also have a Megabyte, it is not reasonable to limit identifiers to anything less than 255 chars! Come on, compiler makers: it's 1986!

More questions regarding shell escapes:

In 3.7i, M-X ! prompts for a command to send to a CLI. It seems to do something, but not very useful. Why do you have to know which CLI is going to get the command? Even being able to do M-X ! dir would be quite useful to me, and COMMAND.TOS from the developers kit does that (admittedly, that's about all it does, but...)

I here apologize to anybody who was inconvenienced.

The real problem, though, is with your mail system: every person on the
machine, subscribing to the same stuff, gets a personal copy mailed,
and has to edit it with a text editor to read it. As I use a nifty
program to sort this stuff out and read SOME, and the (UN*X) system
here gets just one copy of each, the other method seems, well...

Complain to your system administrators! I believe it is possible
to achieve modest levels of convenience even on HAL machines!

Sorry Uwe,

GDOS has NOT been officially released to anyone. There are one or two
unofficial versions floating about out there among a FEW developers.
Unfortunately, I am not one of the fortunate few. Supposedly, GDOS will
be officially released any day now - I'll believe it when I see it.

It probably means that net.micro.atari is being gatewayed into a mailing list
on some other network. When one of the (typically) many sites on such a
mailing list is down or otherwise inaccessable, some of the problem messages
work their way back to the originator.

Actually they should be going to the mailing list or gateway coordinator,
and can usually be ignored...

I too have only a monochrome monitor. The only program that I have run
on my TV is Neochrome, and it is very blurred. The text is also hard

to read. I don't think that using your TV for a monitor is a very
workable idea. If anyone has experienced otherwise, let us know.

This from Personal Computing, Oct. '86:

10 Unexpected Personal Computing Flops
or Under-Achievers

1) PCjr
2) Lisa
3) IBM Portable
4) Jazz
5) Apple III
6) Tandy 2000
7) DEC Rainbow
8) VisiON
9) Amiga
10) Ovation

Does this tell us something? Does anyone know (preferable not
connected with Atari or Commodore) what the *actual* figures
are for machines (ST vs. Amiga) are thru 3rd quarter '86?

I shall change my name to George... curious George, that is.

Aloha,

Jonathan Spangler

I wonder if anyone out there can help me .
I have written a program in M68000 that allows me to open and manipulate a window . Not very hard I must admit but there was one thing I found strange. When I moved the window , the background where the window originally was changes to black instead of the usual grey . Then when I move the window up to the top right , the whole screen goes black . Next , I move the window down to the bottom left and the screen reverts to its normal status .
Sizing the window is fine in the Y direction but not in the X direction .
Its all very strange.
I would appreciate any light that could be cast on this .
Thanks in advance.....(?)

The complaint was the ?Megamax C? had problems with the following code
unsigned x;
while ((x=getchar) != EOF) {   ... }

the complaint was the it went into an infinite loop.
while if x was just an int everything was fine.

He gave an idea that it may have had to do with the
sign extending of char to int.

well the problem acctully is I believe (I don't
have or use magamax c so this is an educated guess)
if you look in STDIO.H you will see that
EOF is declared to be -1.
some c systems use -1 others use 0 i believe.
well the whole point is that -1 is legal and
SOMEWHERE in KR it says so you can have the fun
looking for the little blurb. I seem to
remember it being in the second chapter and

never did see it in the definition if you
really want to find it.

>
Saw an add for the Mark Williams C for the ST. Sells for $179.95 and includes
MicroEMACS, 600 pages of docs, assembler, linker and archiver, and the
Microshell Command Processor (is this Beckmeyer Tools?)

Also: complete K/R "C" + extensions, 8 register variables, full AES & VDI
libraries, UNIX-compatible libraries for portability, 300 Atari-specific
routines, one-step linking & compiling with cc command, English error messages
link-link error checking.

Includes utilites: egrep,sort,diff,cmp,pr,tail,uniq,wc and more.

Don't have it, but it looks really good. PLEASE do not ask me anything else
about this -- I am just passing information along.

Aloha,

Jonathan Spangler

Has anyone out there heard of or written an accessory to perform xmodem file transfers? It seems kinda backwards to me to run a file transfer program in the "foreground" and pull down the emulator program.

In response to bammi%case.csnet@CSNET-RELAY.ARPA:

I don't live on a unix system; the size of my directory and reader are small (I have a 2-cylinder disk for IBMers), so I am always in need of as much space as possible for many things besides info-atari16. I didn't want to get into an argument about this, but I thought I should just emphasize the fact that the people on this list are on MANY different kinds of computers, not just unixes and DEC-20's with +INF directories. There are also many different mail reading programs around; did you notice that I said that there is a program I have tha automatically takes all the info-atari16 files and puts them into a pseudo-digest form for other people to read on my system?

Well, enough of this. I see someone has volunteered to moderate a mod.atari16.sources (or whatever), which might just solve the whole problem.

Hello,
I have upgraded my 520-ST to 1Mb and installed the TOS PROMS myself.
Since this I sometimes have a spontanious keyboard repeat. Also
when no key is pressed. This sometimes resulted in sentences
with a lot of charrrrrrrrrrrrrracters extra. The major problem
is that also KERMIT get hang up (or XMODEM) and I suspect this
keyboard problem. The repetition stops when a , no matter wich, key

is pressed.

Who has also had such problems and knows what to do with it.
With my 1Mb upgrate a heve not use any 68kOhm resistors. Could this
be the cause?

Greetings,

Paul Swanson of Nite-Lite Systems (617) 663-4221 (BBS line) has done some
interfacing of "foreign" disk drives to the ST. I think this includes IBM
PC drives (5.25 inch). He of course would prefer to sell you an interface
rather than telling you how to design one, but he certainly could answer your
questions if he has the time.

The reason is that Usenet is supposed to be used for non-commercial things.
We reasoned that the hard disk driver violates that. Right or wrong?

> About a year ago I was flamed very much by members of Atari (US) and other

Uwe, lets take off the gloves. If you had not posted the program to the
net, we would have had a viable product that we could sell and support. Our
eventual decision to make the CP/M emulator available as a free program was
based on the fact that everyone had it already anyway! A big manual and
support will not be available, sorry, but we just can't afford it.

I like it just the way it is, also living on an IBM system. I don't have the time or patience to track down all sorts of different groups. Half of which I don't receive on the 3B20 via USENET. This group via Arpanet insures I get it all.

Mike

Sounds swell, James, as long as those of us not on the 'net'
can still get to the stuff. (BTW, is there _any_ way, aside
from bugging one of you, of BITNET folks getting at those
archived files? Thanks.)

Uh, if you run a loop 100,000 times in 4 seconds, that is *40* microseconds
per iteration, which sounds a lot more reasonable on a 750. Remember that
this time includes the loop overhead, a function call, and a function return,
and Vaxes are slow about function calls.

Scale all the other "per iteration" numbers by a factor of 10 too.

>Is it possible to select a smaller font (than the default) right before
>calling the draw_string procedure.

I assume you are referring to the draw_string procedure included in OSS's Personal Pascal programming package.

Although there is no specific procedure to change the character height before calling the draw_string procedure, there is a generic VDI procedure which allows the programmer to implement his own such procedures as long as the opcode and other types of parameters are known (via Abacus' Atari GEM Programmer;s Reference Manual). The extra documentation needed to learn how to use the generic VDI and AES routines (oh yeah, there's one for AES routines also) can be obtained from OSS for the cost of the postage, or the literature can be downloaded from there bulletin board. Both telephone numbers are included in the original documentation. To get you going, I've included the code I always use when changing the text height. I hope this helps.

Nick Oddo

Does anyone have any experience with Beckemeyers C-Shell ??
Is it anything like as good as the *real* csh ??

The other CLIs I've used on the ST are not much better than MS-DOS.

Can anyone help ?

Info on any of the other products from this company would be appreciated.

Thanks in advance...

I imagined someone had already thought of that idea before (shortc); I'm
no incredible wizard myself. I'll look for it here at waterloo.
oh, my path is cuae2!clyde!watmath!watnot!cgoudeseune in case you
were wondering.
While i'm bothering you, can you foresee anyone porting smalltalk or actor
to the ST? 1 meg might not be enough, & a hard disk would certainly be
necessary. The reason I ask is, i'm wondering what language to learn next.
C++ seems powerful, but so do the other two. and lisp would be neat too.
sigh. And as i'm taking 9 courses this term (6 is an honours load), i
haven't really got the time to learn them all in enough depth that i'll
know which one to master. Life's weird.
Thanks for your time,
     Camille Goudeseune.

They are supposed to run in the order in which they appear in the folder. This is *not* they order that the desktop lists them, and it is only the order in which they were written if nothing has been deleted. (A deleted file opens up a "slot" into which the next file is placed.) There is no way to list the actual order of files from the desktop, but some command shells have a folder list command that lists the files in their native order rather than sorting them first. So to be safe, start with an empty AUTO folder and then copy in the files in the order that you want them to run.

I have seen a couple of postings on the net about running games on a tv. In the USA, at least, there are several difficulties involved with running high resolution graphics on a television. Almost all the hard places involve stacks of money :-)

In the early days of television the technology was, by todays standards, very poor. Because of the tremendous popularity of "GOLDEN AGE" offerings, millions of dollars were tied up in operating equipment at both ends of the RF path. The resolution of early TV was disgustingly poor. Upgrading the resolution has been a very slow process.

Some of the new receivers available to day can double as a color monitor with very good resolution, but the RF circuitry is still behind the power curve of technology. The biggest problem to overcome in this area is bandwidth. The RF modulators currently available (for reasonable cost) have a bandwidth much to narrow to provide the kind of resolution required by general purpose computers. (Some special purpose computers have been built to provide special effects on television.)

There are ways to "fix" the bandwidth problem, but it would be MUCH cheaper to buy a color monitor from ATARI. If you have a TV that can accept RGB inputs (the current, generally accepted method of overcoming narrow bandwidth problems) it may be possible to extract these signals from the ATARI computer BEFORE the RF modulator. With proper line buffers, thses signals can drive the video portion of the TV. However, unless you can also get at the sync signals, it will be necesary to drive the system through the RF monitor for sync. That means blocking the video signals (preferably at the TV) provided by the RF path and replacing them with the RGB signals.

Bottom Line: Today's Televison Receivers can not do justice to a general purpose computer's capability to draw and print. Computers provide on/off signalling to very small dots (pixels) on the screen. Television signals don't. Computer signals don't try to "fool" the brain as much as TV! :-)

I got uniterm 1.5c working fine, but I can't seem to get keyedit to actually save any key definitions. It creates the files, but they always contain the original Atari values. For example I used the program to set up the cursor keys for EMACS on our VAX. I saved the key defs to EMACS.SET. Then I loaded the file back in again just to check on it. The new defs looked like they were installed. I exited the key edit program and entered uniterm, after loading EMACS.SET nothing was changed. I exited uniterm and went back to Keyedit. When I loaded the EMACS.SET file, everything was back to the original Atari values. I tried saving assembly files, standard files, and even creating a program. I tried defining function keys (F1-10) and even the regular keypad keys (a-z). But the files that Keyedit produced always came out with the standard character set values. Even the assembly file showed no changes in the assigned values. What am I doing wrong? I have a 1040 with color, TOS in ROM.

Any help would be appreciated.

OK, OK, I've complained enough about the Atari ST. Now for something
completely different. Praise!

Two WONDERFUL programs for the ST are: Beckmeyer's Multi-Tasking C Shell,
and Uniterm 1.5.

C-Shell:
     The best. Fantastic. What can I say. If you like Unix, you'll love this. Really does multitask. Really does multiuser. (Really wants 1 meg of RAM, but runs barely in 512K). Pipes, I/O redirection, filters, environment variables, paths, shell scripts, history, aliases... it's real! I can barely tell the difference from this and the Unix system upon which I send this message. I love it! Caveat: Have 1 Meg. Have a hard disk. (I don't know at all how well this runs on a floppy, it's probably quite painful).

     (415) 452-1129
     MT C Shell - $129.95
     Non-MT C Shell (probably also very good, I don't know) $49.95

Uniterm:
     I'm impressed. Smooth scrolling makes me feel cool. VT100 (VT102) emulation makes things useful. The interface is very good. Again, I'm spellbound. The quality of this piece of software is fantastic, and should be emulated (forgive the pun).

Just thought some praise was due.

I of course, have no connection to anything or anyone anywhere, and never say anything that I thought of myself.

-Eric

Does anyone know where I can get XINU for the 68000?
Better yet...how about for the ST?

XINU?

XINU stands for Xinu Is Not Unix.

Does anybody have any advice as to choosing between available hard disks
for the ST? Specifically, does anybody have any information about a
comparison of quality (and, most importantly, speed) between the Supra
and the Atari 20M drives?

And, out of curiosity, does anybody have any idea how they compare (in
speed) to Mac hard drives and XT (or AT) drives?

   If it were important enough you could keep a table of the correspondences
between symbol names and then write a postprocessor to rewrite the correct
symbolic names into the a.out file; this shouldn't be more than a day's work.

If anyone is interested, note that the past few GNU Emacs distributions have
included a simple program that reads C source code and produces a file of
#define statements to map long identifiers into short ones. It also
includes a replacement C Preprocesor (cpp) in case the one you are
currently using doesn't handle arbitrarily long identifiers.

>someone please elaborate on what the enhancements will do?

I have a few other questions about 1st Word as well:

1) Does the new version have ways to make big moves around the screen
without using the mouse? In specific does it have an easy beginning of
line or end of line command (like emacs Ctrl-e)?

2) Is there any way to drive the more "exotic":-) printers like my
NEC 8023? (A general OS print driver (accessory ?) would be nice so that
screen dumps to non-Epson printers would turn out)

3) Is hyphenation supported?

4) Are some of the annoying things about the old vesion corrected like

     a.Outputting a blank page on printing
     b.Exiting the edit file on save (I guess
       I'm in the habit of frequently saving)

For now, 1st Word fills most of my word processing needs but in the future
I may be needing a more complete (spell checking, hyphenation, footnoting,
etc) WP. What other WPs are available and what will they offer.

Thanks in advance,

Bart Atwell

Well, it seems as though the mailer somewhere (I haven't traced it down yet) is expanding the literal $TZ to CST6CDT
(In case it does it to this note, that is dollar sign capital T capital Z, or $ T Z without the spaces)

aka. $TZ (as in REXX variable) is time zone (only guessing, but it makes sense to me) and is being translated to CST (Central Savings Time) 6 (from Greenwich Mean Time difference) CDT (Central Daylight Time). This is a guess, but I will bet that it is either the new version of mail we are using, or a bug in the mailer.

What this means is:
If you received MONST and had long lines, replace the CST6CDT with $TZ and all should be honky-dory.

Let me know,

Mike

p.s. I just sent this to myself with mail and it didn't do it, so
check with your postmaster. I noticed the same problem when I transferred the
file from the 3B20 to the AS/9000N, and just received it without using the
mail exec.

it was written up with only 2 omissions in an old issue of antic (i can give
you the issue # if you want), the first omission was that the atari
disk drives use cmos level signals so you need to stick a buffer chip
in between the drives and second you need to set the access time to 6
ms. there was a pgm called sixms.prg to do that posted to the net, i
have a copy if you need it.

On the flip side of the coin, I have a VCR that I would
very much like to hook into my RGB monitor - of course,
it only generates NTSC Composite signals. Is it possible
to convert this signal? All I have is a black & white
TV for the VCR, and it would be great to have just one
screen for two things (what with space up here being
at a premium and all)

Thanks,
Jon

The latest posting of UniTerm works fine -- thanx a lot, Simon. I also like the ARC program; it makes downloading easier since the files are (a) collated into one file, and (b) compressed.

I have a question about a weird bug(?) that seems related to UniTerm. When I use UniTerm to connect to a remote machine, I can't use Kermit to Send files from my Atari to the remote machine. I can Get files all right, and I can Send files using the same Kermit if I use any other terminal emulator. But if I've used UniTerm in a particular session, then even if I use another emulator without resetting the Atari, this bug appears. What happens is that somewhere between 1500 and 2000 bytes of the file get sent, after which Kermit hangs and eventually times out. I can see it sending some sort of signal periodically, but the remote Kermit doesn't seem to respond, not even to a Quit request. The only way to kill the remote Kermit is to connect to the remote machine, hit a control-Q (upon which I get several error messages from the remote Kermit), undo back to my Kermit, try Quit again (resulting in an "unexpected packet type" message), and finally do Quit again (which brings everything back to normal). This always happens if (and only if) I have used UniTerm to connect to any remote machine before using Kermit.

However, I can use UniTerm to do everything else, such as run a display editor on the remote machine, and even Get files using Kermit; it's only Send that dies.

I suspect what is happening is that UniTerm is redefining some obscure RS232 parameter that no-one else cares about, or perhaps it is redefining something that causes a particular control character to get swallowed up or changed (the character being one that Kermit in one of its protocol sequences). The effect of whatever UniTerm is doing lasts even after it has been exited.

I don't know enough about UniTerm or Kermit's protocols to figure out why this is happening. If anyone has any suggestions, please mail them to me. So far I've been using the Emulator accessory to transfer files and UniTerm for everything else, and I would love to get this straightened out so that I can use UniTerm and nothing but.

Thanx a lot -- Ashwin Ram.

From James M. Turner:

    here's a cute bug in megamax C:

    int c;

     while((c = getchar()) != EOF) {
    .
    .
    .
     }

    works fine but:

    unsigned char c;

     while((c = getchar()) != EOF) {
    .
    .
    .
     }

    loops infinately, the problem is that megamax generates the
    following code:

     AND   #0xff,D0   ;D0 has the result of getchar
     CMP   #-1,D0   ;ooppsss should be CMP.B

As well it should! EOF is -1. An "unsigned" number is always
positive and hence can never equal a negative number. The reason
c must be an int and not a char is that getchar() might return any
any of 256 valid bytes as well as the EOF indicator -- 257 values
in all, and they won't fit into 8 bits.

There is an outfit in california that will replace the innards of
a single sided drive, to a double sided one. I cannot offhand remember
their name, but their ads used to appear in ST applications and maybe
in other mags too. I seem to remember they wanted around $100.

If the rumor about GDOS being distributed to developers in the US is true, I haven't heard anything about it (yes, I am a registered developer). My understanding is that certain developers like MiGraph (EASY-DRAW) received preliminary copies, but that it has not yet been generally released. I do recall reading a series of messages on the ATARIDEV Forum on CompuServe in which several well-known developers complained about not having GDOS. These were Batteries Included and MichTron, I believe. Come on guys, where's the GDOS for the rest of us?

I have been able to decode most of the recent uuencoded postings- ARC, ARC Lite, Mandlxbox, Clock, Tbug, the Arc shell,EMacs7.1- without too much difficulty even though I am on an IBM machine, a 3084 Q, on bitnet. The only exception was Uniterm. However there were hardware incompatibilities, perhaps there is a hardware problem with the latest version of Uniterm - only works with a hard disk, or with Simon Poole's latest setup.

I have two 1040's one with color monitor, one black and white. Arc Lite only runs with the color monitor, it hangs with the black and white one. Mandlxbox only works for me if I first load a 512K ram disk, its bombs on my 1040 with the full 1 meg of memory available. Uniterm bombs as described by others; however the keyedit program works fine and I see no unusual distribution of characters in the UUencoded files.

In a check of the WISCVM gateway last summer (made by D. Moews) UUencoded files passed OK from Arpanet to Bitnet and from Bitnet to Arpanet. Why then does Keyedit work and not Uniterm?

By the way the spaces in the uucoded emacs and the arc shell were X'79's instead of x'40's I had to convert them for my version of UUdecode.

There is a program called 'bmodem' availible from BIX in source and binary
for the ST that has scripts. It think it has large (1K) packets. I haven't
looked it over yet, so I don't know what other features it may have.

The recently posted MANDLBOX demo works with a color monitor (, 512K and
TOS in ROM) I don't have a Black and White, but I'll send sources and
a suggested strategy (actually its pretty simple) to someone who has:
1) a Black and White, 2) Developer's C, and 3) the desire, and I'll strongly
consider back integrateing it.

This last week has been a very difficult one for moderating info-atari.
Our input message queue exceeded the size which the mailer could
hndle; so we were unable to process messages for a period.

This problem was caused by some moderators failing to work their assigned
days and by an influx of rejected messages. The first problem can be solved
by more volunteers. I again encourage you to offer to help keep this
service going.

The second problem can be reduced by a more immediate response to
rejected messages. Henceforth messages which indicate that there
is an error in the destination address will result in immediate
removal of the offending address from the list. I7m sorry to have to
do this, but I see no alternative.

```
--------------------------
| SPELL 1.3 User's Guide |
--------------------------
```

HOW TO USE THE SPELL PROGRAM:

SPELL is a program that allows you to detect and correct spelling mistakes in disk files. SPELL should work with files produced by just about any word processor. SPELL has been tested on files produced by the 1ST WORD

word processor.

THE WORD LIST:

SPELL uses a disk file named "words.txt". This file contains all words that SPELL recognizes as being correctly spelled. When you start using SPELL, this file will be empty, and SPELL will wonder if every word in your document is misspelled. As you check the spelling of more and more files, SPELL will know about more and more words. Eventually SPELL will have a dictionary containing most of the words that you use, and will only ask you if misspelled and unfamiliar words are misspelled.

RUNNING THE PROGRAM:

When the program is first run, the file "words.txt" is created on the default disk. Make sure that SPELL has write access to the disk on which SPELL is stored.

Then all words stored in the file "words.txt" are loaded into memory. If SPELL is being run for the first time, no words will be loaded.

Now you are asked for the name of the file for which the spelling is to be corrected. Enter the filename that you want checked. SPELL must have write access to this file.

After the file to be spelled is specified, whenever SPELL encounters a word that is not in the file words.txt, you may:

(1) correct the spelling of the word
(2) add the word to the dictionary

To correct the spelling of the word, type in the word as you would like it to appear in the document being checked.

If the word is correctly spelled, or if you've just corrected it, then you may want to insert it into the dictionary. To add the word to the dictionary, place the mouse in the appropriate box and press the left mouse button. When you add a word to the dictionary, whenever SPELL sees that word again, it will know that it is correctly spelled, and will not ask you about it.

UPDATING THE DICTIONARY:

Why do you need to update the dictionary? Well, every time you start the program, the dictionary contains all the words that were in the file "words.txt". As you insert new words into the dictionary they are stored in your computer's main memory, and are NOT placed in the disk file "words.txt".

If you choose to update the dictionary by pressing the left mouse button in the "yes" box, the new words in main memory will be inserted into the

file "words.txt". When the program is done, "words.txt" will contain all the
words it had before running SPELL, and also the new ones you inserted.
When you run SPELL again, it will know that the new words are correct, and
and will not ask you about them when it encounters them.

If you choose not to update the dictionary by pressing the left mouse button
in the "no" box, the file "words.txt" will not be changed - it will have
the same words that it had when you started running SPELL, and will not have
the new words that you inserted when SPELL was running.

FOR MORE INFORMATION:

If you would like more information about SPELL, please send a stamped,
self-addressed envelope to the following address:

I'll second this and in addition: What about the non-developers? Do we
just never get updates (->HDX). BTW nobody even knows HDX is broken or
that the 40 subdirectory "feature" exists here, I tried to get the local
shop to at least warn the people about these problems...

I *HAVEN'T* had enough! While I agree that some convention should be established so that a person could tell by the Subject field if the message contains source or UUENCODED executable, I signed up to this news group because it does have such a large volume of information. Maybe people who develop software should just place an announcement on the net, and then collect a list of those who respond, and mail just to them. I don't think so: personally, I very much enjoy getting the quality of software displayed recently by ARC, ARCSHELL, UNITERM, and UEMACS for **Free** and without the hassle of mailing disks to someone to get a copy.

And isn't one of the reasons the news group exists in the first place to teach new users about the capabilities of the machine? If so, you can surely expect some redundancy in message topics, since new folk are added to the list constantly (I imagine).

So, to all those people who have been taking the time to develop, encode, and mail programs to the net, thank you very much. If something comes up again and it's decided that no source or encoded material will be allowed, please go ahead and put my address on your own mailing list: I want the *opportunity* to decide whether I want a copy or not.

Summary: price

In a message it was said that the drop in price of the 1040 could be
due to the very bad sales.
This I know not to be true. One of the main reasons for the 1040 to
drop in price both in Holland as in Germany is that official dealers
had (have?) a lot of competition from non-dealers, who imported the
machine 'illegaly' (outside Atari channels). They would sell it for
a few hundred bucks under de official Atari price. Aparently, this was
the solution to the problem.
The 1040 sells very well (at least in Holland it does).

Summary: function call overhead reviewed
Xref: mnetor net.lang.c++:369 net.micro.atari16:2503

[]

If 100000 calls take 4 seconds, that's 40 uS per call, not 4.

BTW, the 100 uS time I mentioned is for sending a method-token
to an object, complete with the lookup and the late binding.
And it is on the Atari ST. For comparision, a standard C function

call (passing an integer both ways) has a 25 uS overhead, approximately.
Of course, any useful function (or method) would take at least another
20 uS to do its thing, and usually a lot longer.

- Moshe Braner

PS: I got many requests for the Object-Oriented C Programming.
I'll prepare a posting, one of these days.

Summary: NOT a bug!!

[]

EOF is NOT a char, not even an unsigned one. Also, all
operations (e.g. the "c==EOF") are done with int's, not
chars. Therefore you should declare c an int, as dictated
by K&R in the bible...

BTW, using chars, signed or unsigned, wastes time: it adds EXT.W
to convert it into an int... (or the AND #0xFF if unsigned).
Use the char type only for arrays, to save RAM.

> tens of kilo chars in size of what looks like a drunk writing
> teco macros?

I don't know --- I kind of like getting free software (and you must admit
that most of the stuff that has been coming over the net recently is both
good and useful -- thanx, guys). I find it a trivial flex of my right finger

to hit "n" if I don't want to read a particular note, and most people are pretty good about warning us about large files coming up in following messages. "Shareware" is a great concept, and I for one would vote for its continuation.

> My poor mail file blows up and chokes MM more frequently with such stuff. why cant people just send a pointer to their program and let those who want it get it or request it individualy. It used to be considered anti-social to send such masssive files unsolicited.
>
> --E+

One problem with sending it to everyone who wants it individually is that that generates a *lot* of net traffic when a lot of people want something large like uEmacs (which a lot of people *do* want). Many sites are set up such that USENET notesfiles are transmitted *once* to the site, and then either (a) individually transmitted to local users (not expensive) or (b) posted on a publicly readable bulletin board or notesfile which individual readers can read using rn/readnews/notes/... (not expensive either). The situation is complex. You may have a point regarding large pieces of software that is interesting to very few people, but it isn't as simple as "don't post shareware, period". For obvious reasons, "getting it yourself" (i.e., FTP, etc.) isn't a practical solution either.

The right way to cut down costs, in my opinion, is to (a) encourage sites to provide a single mailing address for mailing lists in cases when there are several users at that site interested in the mailing list, rather than each user being on the mailing list individually, and (b) reduce the number of bouncebacks (which generate a *lot* of net traffic). Marshall has already taken some positive steps in the latter direction.

Finally, someone got it to work! The "problem" is that I sent only
one *.sng and *.pic file with alite.prg. I had thought of distributing
some more of the *.sng/*.pic combos, but decided not to (in light of all
the recent grumblings about large volumes of mail). Those of you wishing
to acquire more of the original alite music should send email to me, and
I'll email the stuff directly to you.

>

    Oops, I guess I stand corrected. Of course, I've always believed that if something dosen't work for certain isolated cases, it simply dosent work, however, I suppose that if it means we *CAN* have C++ on an ST, this is something we could learn to live with. (Provided, of course, that you don't mind not being able to count on a given (correct) program compiling.) Where do I order my Cfront?

your point is well taken but allow me to play devil's advocate...

1) the question of size and cost doesn't need restating, the sources for
emacs are about 400K

2) not everybody has the same compilers, but we all have ST's

3) for evolving programs like emacs and others, posting the sources
is an open invitation to chaos, it guarentees that there will be almost
as many versions of the program as there are people with good ideas
making the introduction of new versions a nightmare

I think the complaint is valid. In the Mac world, we have long
had net.micro.mac and net.sources.mac (a misnomer: there are
about 100 times as many binaries as sources in net.sources.mac).
So why not net.micro.atari16.sources and/or net.micro.atari16.binary?
Then the sites who don't want programs don't even have to have them
uucp'd to themselves.

I also think the original poster may have been complaining about
true garbage, i.e., a few recent uuencodes that went sour somewhere.
This should, of course, be avoided as much as possible, but we're
all only human, after all.

Product: ST-TeX
Vendor: Tools Gmbh
         Kaiserstrasse 48
         5300 Bonn 1
Phone: 0228/229791
Price: $150 ($5 shipping)

This is TeX, Version 1.5 for the ST [0.9x] (no format preloaded)

... and they aren't kidding. We just received a preliminary version
of ST-TeX which is being prepared for the American (English speaking)
ST market by Tools Gmbh. It arrived on six double sided floppies
consisting of TeX itself, a DVI GEM-based previewer, TFM files,
font files, LaTeX format and style files, and IniTeX.

We took two LaTeX files, a mathematical screed on timed Petri nets
and a pictorial introduction to digital system synthesis, and ran
both through without problems or modification. Speed with a hard
disk is roughly equivalent to LaTeX on a 780. If you are split
across two or more machines (and most of us here use an ST, VAX
and/or Apollo daily) you might want to standardize your format and

style files as I've noticed subtle differences such as bold
for description items on the ST and italics on the VAX.

The previewer is wonderful. The scroll bars slide the window around
a page so you can examine every nook and cranny. It is faster than
the Apollo previewer from Yale. Currently, FX-85 Epson compatible
printers are supported. The printed output is great given the 9-pin
head. Make sure you have a big print buffer though -- our standard
buffer size Panasonic 1092 truncates each line. Buffer expansion
options are now on order. Print time is about 6-8 minutes per page.

Tools Gmbh emphasizes that this version is preliminary and that a
newer version will be available near the end of the month. There are
a few problems:

1. The version received needs a full 1 Mbyte of RAM. If you own a
   520, it's time to upgrade.
2. Directory searching is not fully implemented. Hence, you need
   to drop a hint to the previewer as to the location of the
   screen or printer files, TEX.TOS must reside in the same
   directory as the TeX input and format files, etc.
3. There are so many files that a single DSDD drive system may
   not cut it. A hard disk is strongly recommended.

Tools Gmbh is currently looking for a USA distributer. Since we're
nice guys in a hurry, we convinced Tools Gmbh to sell us a copy.
They do NOT encourage direct sales right now. (We had to draw an
international bank draft and Federal Express'd the order -- I said
we were in a hurry.)

This product is strongly recommended.

this is new to me, so please keep flames to the lit match at 20
paces level

there has been some very real problems with posting source and
binaries to net.micro.atari16, uuencode didn't work properly or a
file was too large and got truncated, and reposts requests and their
answers abound. therefore (deep breath taken) i propose to moderate
mod.sources.atari16 with associated archives. programs will be
unshar'd, uudecoded, downloaded and tested before they are
distributed, also care will be taken to make sure that no posting is
too large and Subject lines will be standardized with catalog
numbers etc. (what am i getting myself into??). if i do not hear an
overwhelming 'nay' vote by Oct 31st i will create the group and
issue specific instruction (where to mail etc.) for the group.

> and other addon and end user products.

In this case, we feel it is important enough for the total marketability of
the ST to devote the resources to the PC emulator.

That doesn't mean that you or I want them, but lots of business types do.

[Is the line eater Hayes compatible ...]

I was in a local discount computer outlet today and saw two versions of the Avatek 1200 modem, one was called the 'Avatek 1200' and the other was called the 'Avatek 1200hc'. They were going for $80 and $140 each, respectively. The salesperson implied that the former was 90% Hayes compatible while the latter was 100% compatible and thus cost more. I picked up and read the manuals for both, and a quick (5 minute) browsing through the sections on command sequences, instructions, and warnings, etc., failed to any difference between the two. There were no other differences that I could see anywhere on the two boxes: just a little 'hc' after the 1200 on the one that was $60 more.

Does anyone out there in netland have any idea what the difference between these two could possibly be? I seem to remember a long discussion on Avatek a couple of months ago, but did not pay any attention to it. Maybe someone remebers and can tell me if it had anything to do with this. Can anyone with an Avatek modem report any results of trying to use it as a Hayes compatible modem?

Please mail replies to me. I will post results to net sometime next week if there is interest. Thanks in advance.

Summary: Truncated file

Our copy of 'ARCSHELL' part 1 was badly truncated. We didn't even receive the 1st of the 3 modules in complete form. Could part 1 be reposted? Also, Upon trying to compile Part 2, I found that I was missing 2 .SYM files (and I would therefore expect also the .LNK files). One, I think was the BIOS.SYM. Assuming this is proper material for posting (I *am* a legal licence holder for the TDI compiler and I did *not* receive the relevant files), could someone send me a copy of the relevant files? Message me via 'mail' and I'll check which files I need.

Cheers! -- Jim O.

Has anyone noticed that *very* few reviews of games (and software in general)
for the ST mention what the thing looks like through the RF modulator? For
instance, can anyone tell me if The Pawn is enjoyable on a color TV rather
than the monitor? I doubt any store owner is going to let me borrow a package
for the night in order to test it on my TV, and monochrome is all I could
afford (and besides, I like it).

I would be very interested in hearing from you if you've successfully or
unsuccessfully run a commercial package, game or otherwise, on a home TV.
Thanks for your comments.

Here is my method for object-oriented programming in C.
Please direct comments to <braner@amvax.tn.cornell.edu>
or to the address above.

- Moshe Braner

~~~~~~

Framework for object-oriented programming in C.
==========

Copyright (C) 1986 by Moshe Braner.

Permission is here granted for noncommercial use. The selling
of this document or the code included in it, or parts of either,
in printed or machine-readable form, is expressedly prohibited,
unless given written permission from the author.

Objects are allocated memory at run time. The structure of an
object (an instance of a class):

A pointer to the object's class.

In case the object inherits any properties from a
superclass, a pointer to the object's "superinstance"
(just another object, an instance of the superclass).
~~~~~~

In addition, the object may hold instance variables.

Class definitions are set up at compile time. The structure of a class definition includes:

A "typedef struct" describing the objects in the class (always as above).

A #define giving a symbolic name to each method-token. This may be put in the central header file of the application, for easy cross-reference, or may be left next to the class definition. The token values (positive integers) need not be unique across branches of the tree of classes, but they have to be increasing along the inheritance pathways.

The method functions, which manipulate the objects of this class in the noninherited ways. The names of these functions should not be repeated in the same source file. A method function is always of type "int", and usually returns error codes, but may return other information. It always receives a pointer to the object being manipulated ("receiving the message"), as the first argument, possibly followed by others. Initialization and clean-up methods, if defined, must return ERROR (-1) if errors were encountered, OK (0) otherwise. To reduce the verbosity of the method definitions, three macros are defined in the file objects.h: DefMethod, ArgMethod, and ENDOK.

An array of METHODs (initialized at compile time), each of which contains a token (actually an integer) and a pointer to the actual function. (A typedef struct of the METHOD element is also in the file objects.h.) The last entry in this table has to be {NULL, NULL}. (To reduce the verbosity of this declaration, the macros MTable and ENDMT are in objects.h.) At run time this array is searched sequentially, so the methods to be called more often should be placed at the beginning of the array. Methods may override superclass methods, intentionally or not, simply by taking on the same tokens, or the same token values. (Initialization and clean-up methods, if defined, must be included in this table, are always given the same tokens as any similar functions belonging to any other class: OBINIT and OBCLEAN (#defined in objects.h). This does NOT mask the superclass' counterpart because Create() and Destroy() also call the superclass methods directly.)

An actual "CLASS" structure holding a pointer to the

methods table, a pointer to the superclass, the size of an object of this class, and flag bits indicating whether the objects in this class need to be initialized when created (CFINIT), and whether they have a clean-up method to be called before destroying them (CFCLEAN). (A typedef struct of this construct is in the header file objects.h.)

There are three generic object-manipulating functions, defined in the file objects.c:

Create(class-name) (#defined into cCreate(class-address) creates a new instance of the class, and returns a pointer to the new object (or NULL if allocation failed). Recursively creates the super-instances, automatically.

Destroy(object-pointer) frees up the memory in an object. Recursively destroys all the super-instances, automatically. Returns OK or ERROR.

The call to a method ("sending a message"):

```
    Do(method-token, object-pointer));
```

or

```
    Do(method-token, object-pointer),arguments);
```

(note the unusual syntax with unbalanced parens!). This is actually #defined into the form:

```
    (*FindMethod(token, object))(object,arguments);
```

The generic function FindMethod() searches the method list, pointed to by the object, for the method token. If not found, the superinstances are searched in reverse order of inheritance. FindMethod returns a pointer to the method, which is promptly used to call the method itself. Since FindMethod() is called very often, it might be optimized in assembler language, although my tests (MC68000) show little improvement.

More complicated data structures (such as arrays or lists of objects) are not part of this basic system but may be easily added by defining new classes of objects. For example, an "array of data objects" may be an object holding the dimension of the array and an array of pointers, and would have an auto-initialization method that creates the "data objects", and an auto-clean-up method that destroys them. A "linked list of objects" may be constructed using "ListNode" objects (just pointers to an object and the next node), and "List" objects that only hold a pointer to the first node, but have access to methods for adding nodes to the list, removing them, etc.

Here is the actual C code:

```
--------------------------

/* File: Object.h   - by Moshe Braner, 860813 */
/* --------------   ------------------------ */

/*
 * The basic syntax aid to calling a method:
 */
extern int (*FindMethod())();

Is it possible to select a smaller font (than the default) right before
calling the draw_string procedure?

Thanks in advance,

Would anyone like to expand on how to use 1st Word REFORMAT command?
For example, if I pull in an 80 column ASCII file, and want to reduce it
to, say 62 columns, shouldn't I be able to do this with REFORMAT? It seems
that once I type without wordwrap on, the REFORMATTING no longer is effective.

What's the story??

Thanks in advance, Ron Kushnier

I am a non-ST-owner interested in information on STs. I have zero use for actual code. I have generally not saved any of the code that went whizzing by. I figure that when and if I buy an ST, most of what is available now will still be available for the asking, and probably several bug-fix versions later.

I would vote for descriptions of what programs are available and mailing of actual source or object code only to those who care enough to ask. That would also solve the "source vs. object" controversy.

So, here it comes again!!! This is not really a repost since I've changed
a few things from 1.4 to the current version 1.5c. In particular it works
correctlly with a color monitor now (not flashy but it works!). I've
sent this posting to a few people in the US on ARPANET and BITNET and they
all were able to uudecode and unarc it...and I haven't touched it since!!!!!

The complete posting is:

To answer several people's questions.

The Formatter does not modify the operating system in anyway. It is a
stand-alone program which has the modified format code in it. You can use
the formatted disks just as you would a normal disk. TOS has no idea that the
disks are different, unless one is 80 and the other is 82 tracks. You can do
disk copies or file copies of disks, assumming that the format size (tracks

and sectors) of the two disks are the same.

What the formatting algorithm does is this. Bad sectors are placed at the end of all the tracks formatted. When the WD1772 hits a bad sector, BOOM! the chip stops instantly with an error, and goes to the next track. In this way, the WD1772 doesn't have to wait for synch info, it just goes.

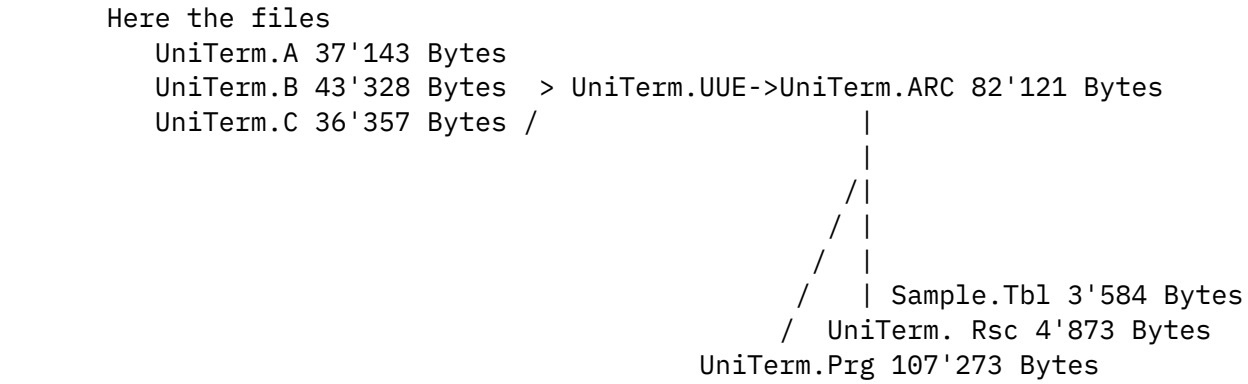
READ.ME for UniTerm V1.5c

UUDECODING UniTerm

You should have following files:



UniTerm incompatibilities with VT100 software

-only 128*24 (64 in double width/height mode) characters in 132 column mode
 (selecting this mode turns autowrap off to prevent lines wraping around,
 but you can always select autowrap manually or with the proper command
 sequence), no cursor
-no double width characters on color screen and in 49 row mode
-no self tests (do you really want to do this to your computer:
                "Repeat Selected Test(s) indefinitely (until failure
                 or power off)" (C) DEC)
-no interlace
-no autorepeat control
-no smooth scroll down

Other Problems

-DEL as a padding character in Tek alpha mode is not suppressed
             - solution: change padding character to NUL
             - or wait for my binary patch (coming tomorrow)

Differences to V1.2

-proper line drawing character set in 80 and 132 column mode!

-real nice character set in Tek4010 alpha mode
-VT52 mode
-128 columns * 24 rows mode
-input buffer size is 10'000 bytes
- <Alternate><Y> stops screen output
- <Alternate><.> toggles 49 / 24 row mode on monochrome screen
-a keyboardtable is loaded with the setup file
-a GS received in VT... mode switches to Tek4010 vector mode, but a CR,US or
 ESC FF returns to Tek4010 alpha mode (this is the way everybody does it!)
 this means you always have to switch manually back to VT... mode (<Alternate>
 <F6>) except if you get a CAN which always (well nearly always (there's a
 undocumented feature here!)) switches the screen back to the text screen
 and sets VT... mode.
-VTTEST compatible, except for the bug in the terminal reports section
 (I mean the bug in VTTEST)
 (try VTTEST with a real VT100 or with VTCOM on a DEC Pro 380, you'll
  be suprised)
-a lot of bugs fixed, including
    -last character of single-line editor is not lost
    -tab works properly
    -wrap works like on a VT100
    -ANSI insert/delete line and delete character commands
     work properly with scrolling regions
    -shifted function keys work
    ....
    ....
-a lot of other things.............
-one last thing, in a late midnight hack I added a input translation
 table to the file-capture function, beware: it hasn't been tested
 at all!
 <Alternate><O> allows you to select between |Raw|Trans|Load|
 Default is Trans with a default table that has a negative entry
 for NUL and DEL (this means they are ignored!). Load, loads a table
 in the format of the sample table supplied with this posting.
 >>>>I know this is horrible<<<<<

Thanks to all the people which reported bugs and made suggestions
(which naturally are still welcome), if I didn't answer your mail it
probaly was because I have a lot of trouble sending mail to sites
not on Bitnet or Arpanet.

Agreed. But there is no need to cross-post to all the various pc groups!!
Enough is enough. Lets have more of the useful discussions, relative to
the specific groups, that had given the net its reputation for an excellent
source of fast and pertinent information and news.

Well, I've learned my lesson. When posting the net I promise to:

     1) uuencode on my ST
     2) upload to my Pyramid
     3) download to my ST
     4) uudecode on my ST
     5) verify uudecoded program
     6) post to net if ok

So, after having done all of the above, here is ARC again:

```
#! /bin/sh
# To extract, remove mail header lines and type "sh filename"
echo x - arc.doc
sed -e 's/^X//' > arc.doc << '!FaR!OuT!'
XARC Introduction and short docs.
X          ARC (short for archive) is a file library and compression
X          utility.  It may be thought of as an improved version
X          of LU and SQUEEZE all rolled into one program.
X
X          ARC analyzes each file to see which of a number of
X          compression techniques will generate the smallest code.
X          The following estimates give the user a general idea of
X          how much compression may be gained by using ARC.
X
X                ARC Text -            45-55% reduction from original
X                SQUEEZED Text -       30-40% reduction
X
X                ARC Programs -        25-30% reduction
X                SQUEEZED Programs -   15-20% reduction
X
X                ARC Pictures -        45-55% reduction
X                SQUEEZED Pictures -   40-50% reduction
X                TINY Pictures -       40-50% reduction
X
```

X   The user should see that compressing files with ARC
X   will allow easier telecommunications by combining files
X   and shortening their transfer time.
X
X   Usage from TOS
X   - double-click-left on ARC.TTP icon
X   - observe OPEN APPLICATION menu for ARC.TTP parameters
X   - enter switch, archive name and file template
X   (ex: lh arc.arc *.*)
X   - hit return or click-left on OK box to begin execution
X   - "press any key to continue" after completion
X
X   History
X   ARC has been in use in the CP/M and MS-DOS world for many
X   years. Thom Henderson developed the version which I
X   converted for use on the Atari ST. I am not sure but he
X   may also be the original author.
X
X   It is important to note that no matter who developed this
X   program, ARC is based on the file compression theories
X   developed by Huffman, Welch, Knott, Knuth, and many other
X   scientists.
X
X   Bug Reports
X   Since I developed this version of ARC, I will be responsible
X   for any erroneous features. Please relay any problems with
X   a written discription of what happened and the .ARC file
X   which caused the problem to:
X
X   Harvey Johnson
X   2398 Oaklyn St NE
X   Palm Bay, FL 32907
X
X   - or -
X
X   QUILL BBS 305-724-2303
X
X
X   Future Products
X   It would be nice to have a version of ARC written to utilize
X   GEM. I would also like to write a picture display feature
X   that will show compressed pictures directly to the screen.
X   This will be useful in that ARC squeezes file 5 to 10% smaller
X   than TINY format. If anyone has the C source to dump NEO,
X   Degas, or other pictures to the screen please upload a copy
X   to QUILL BBS.
X
X   If you have any ideas for additional capabilities, then send
X   them to me with a detailed explanation. All thoughts are
X   welcome.
X
X   Donations
X   It would be nice to be supported if you think that ARC

```
X          is any good.  Make no mistake, I did NOT write the original
X          version of ARC, but I have spent all my extra time for
X          two months making it a reality on the Atari ST.
X
X          As I do recieve contributions, I will consider improvements
X          more seriously.  Any donations may be sent to address
X          specified in Bug Report section.
X
X          Thank you one and all in advance for considering this
X          request, but if you are like me (lazy) then I don't
X          really expect to ever see a single dime.
X
XARCHIVE (ARC.TTP)
X
X     Usage
X          arc {amdxelvth} <filename.ARC> [<filename> ...]
X
X               a   = add files to archive
X               m   = move files to archive
X               d   = delete files in archive
X               x,e = extract files from archive
X               l   = list files in archive
X               v   = verbose listing of files in archive
X               t   = test archive integrity
X               h   = hold screen before returning to Desktop
X
X     Description
X          This program is a general archive utility, and is
X          used to maintain an archive of files.  An "archive"
X          is a single file that combines many files, reducing
X          storage space and allowing multiple files to be
X          handled as one.
X     Switches
X
X          a - add files to archive.  This switch will force update
X              or addition the indicated reguardless of creation
X              time and date.
X
X          m - move files to archive.  Same as "a" switch except
X              that the files are deleted from the directory as
X              they are moved to the archive.
X
X          d - delete files in archive.  The files are lost forever
X              and the archive is recompacted to remove the data
X              for these files.
X
X          x,e - extract files from archive.  A copy of the files
X              in the archive are created in the current directory
X              in an uncompacted state.
X
X          l - list files in archive.  Limited information listing
X              of files contained in an archive.  Displays only the
X              filename.
```

```
X
X          v - verbose listing of files in archive.  Complete
X              information listing of files contained in an archive.
X              Displays the filename, original length, storage method,
X              storage factor (% savings), compacted size, date, time,
X              and CRC.
X
X          t - test archive integrity.  Check the archive to make sure
X              it does not have any bad files contained.
X
X          h - hold screen before returning to Desktop.  This switch
X              should be used whenever ARC is executed from the
X              Desktop, except in conjunction with file redirection.
X
X     Examples when executed from GEM Desktop:
X
X     ah FILES.ARC *.PRG      Creates a new archive file called FILES.ARC
X                             and puts all files ending in .PRG inside.
X
X     xh FILES.ARC *.*        Extracts all files from FILES.ARC.
X     xh FILES.ARC            ""
X     xh FILES                ""
X
X     xh FILES.ARC *.DOC      Extracts all files ending in .DOC.
X
X     In each case, the 'h' holds the display instead of immediately returning
X     to the GEM Desktop so you can view filenames, messages, etc.
X     These are just to help you get started.  ARC seems to be the most
X     reliable of the 'masher' programs and has the best overall size
X     reduction.
X

This is a repost of alite, a midi/graphics demo available from CIS. Extract
the shar file below and run it through sh to get the files "readme" and
"alite.uue". Run alite.uue through uudecode to get the ARC archived file
"alite.arc". Finally (phew), use the latest version of ARC to extract
the files "alite.prg", "1alite.sng", and "1alite.pic". See "readme" for
more info.

Don't you hate those guys that don't know how to post anything to the net?

-Rich

#! /bin/sh
To extract, remove mail header lines and type "sh filename"
echo x - readme
sed -e 's/^X//' > readme << '!FaR!OuT!'
XHere is my test case for ARC. Uudecode the file alite.uue and you'll end
Xup with alite.arc. You may then use the "x" option in ARC to extract the
Xfollowing files:
X
X   alite.prg
X   1alite.sng
X   1alite.pic
X
XLet's all start using ARC and we can cut down considerably the amount of
Xtime and money we spend uploading/downloading software.
X
XAlite.prg was written by the fellows who brought you The Music Studio (tm)
Xand was posted nearly a year ago on CIS. Basically, it is a MIDI/graphics
Xdemo with a pronounced yuletide flavor. However, you can also use it to
Xplay all those *.sng files floating around out there. To do so, you must
Xdo the following:

```
X
X    1) move the *.sng file to the same disk as alite.prg
X    2) rename the *.sng file 1alite.sng (or 2alite.sng, 3alite.sng,...)
X    3) make sure a corresponding 1alite.pic file is on the disk
X    4) execute alite.prg, the rest is easy
X
XI've included 1alite.sng and 1alite.pic in this posting to get you started.
X
X-Rich

A distant friend of mine recently purchased the 20M Atari hard disk. New to
the microcomputer world, he was told that he needed to run the head park
routine every night. Is this on the level? I told him it seemed to me that
he should run it if he was going to be moving the system, but otherwise not.

Also, a local dealer said VIP, PC/Intercomm, and some printer program (I for-
get the name) would not run on the hard disk (??!!??). Was the dealer
referring to copy protection? Surely the individual programs couldn't care
less where they are stored and loaded from.

As usual, verbose comments are encouraged, though all are appreciated...

Hello,

Who could sent me a unsqueeze program, either uudecoded or C-source?
And second:, How can I make a normal file from all the Shell-archive
mailings I get all the time? (e.g. from BAMI)

Greetings,
Berend F. de Vries,

Hi,

My friend has a 1040 with a Panasonic 1091 printer; when he prints a document
from 1ST_Word, the computer locks whenever he tries to print more than 3 copies
of a document. The computer also locks when he exits BREAKOUT.ACC. Any ideas?

our VAX using XMODEM with Ansigraf. In order to get the proper carriage returns and avoid overflowing the input buffer on the VAX, we need to use the "T" option when XMODEM on the VAX is invoked: 'ST filename.ext' to send a file from the VAX to the ST, or 'RT filename.ext' to send a file from the ST to the VAX. Then run XMODEM in Ansigraf in the appropriate (send or receive) mode.
     These comments apply to ASCII text files - haven't tried binary files as yet.

Hello,

   I had the same problem with UNITERM. I UUDECODED it, and when it runs without the RSC it runs fine, and tells me BYE,BYE. But with it, it freezes up, and after loading, I end up looking at a desktop screen with UNITERM.PRG written at the top. Any ideas?

Rick

     Several people have asked if I will post the list of software
which works with Magic Sac.

     I am going to try all of the software I have on my Mac at work
starting this weekend, and will post both the Data Pacific list, and my
experiences.

The first installment will probably be Monday or Tuesday of next week.

Marty

If your compiler is capable of handling 32 character variable names, you should normally not have any problems with using C++. There may be isolated cases where problems would occur, but the names that the C++ compiler generates are usually unique in the first 32 characters. Of course, it would be nice if one of the C vendors for the ST would provide a true flexname capability. It really isn't very difficult to do!

i heard that there were problems with VIP amoungst others on a hard
disk but i believe most of the problems were solved by having the program
and any associated files in the top level directory because the
program was too stupid to look in the current directory, rather it

assumed that it was the only thing on the disk

Summary: Disconnect phone line during thunderstorms

[]

I've had my Avatex modem fried, and also the 1488 chip in the ST, during a thunderstorm in August. Since then I PHYSICALLY DISCONNECT the power line and the phone line during bad weather. (When it happened, only the phone line was connected.) The phone company told me the surge arrestors outside were blown, so I really had a strong hit, which is rare but...

BTW this was second time I had to send my AVATEX 1200 modem to their service center (E&E DATACOMM). Their service was quick (well, a month, but half of that on UPS shipping back and forth) and they have a small flat fee (if it's not under warranty). So my experience is: If you fear buying that cheap modem because of lack of service, fear not.

Summary: How to fix the 1040 main unit whine

[]

Due to repeated requests, a reposting:

~~~~~~

Atari has issued a technical note to its dealers about the high-
pitched whine in the 1040. I hope I am not stepping on anybody's
toes in posting this here.

The whine is at about 16 KHz, which most people who grew up with TV
cannot hear. I love the SM124 B/W monitor because it's silent (35 KHz
scan rate), but the whine from the computer still bothered me.
I thought it comes from the main power-supply, but the note says it's
from the circuit around the "converter" chip on the mother board (U62).
This chip makes negative voltage from the positive (using an oscillator and
a "multiplier" rectifier arrangement?). The fix for the whine is to raise
the frequency, by RAISING the values of a resistor, a capacitor and an
inductor. The latter claim is against all my electronic instincts, but I
tried it and it works. Here is how you do it:

Obtain a 5 ohm 1/4 W resistor, a 330 pF capacitor, and a small, axial,
220 microH inductor. Take the top cover off the 1040ST (unscrew the short,
self-tapping screws from the bottom). Take the metal cover off the
power-supply module (one little screw holds it down) and remove the module
itself (two screws at the two corners on the keyboard side).
Just "north" of the power-supply-module connector you will find U62.
Locate R17 (north of U62, 1 ohm), C28 (third component on the west, 100 pF,
looks like a resistor), and L4 (east, 100 microH, looks like a big resistor).
Replace them with the new components. That's it.

There is a pair of wires, blue and red, going from the U62 area towards the
RS232 interface area. The red wire carries +8V or so, relative to ground.
The blue carries the negative, and I measured -7V on it after the fix.
(I expected -12V, but 7 is close to 8 and the computer works fine...).
If you don't get good negative voltage on the blue wire, relative to
ground (not the red wire), you may have stopped the oscillations in U62.
Try a different L4, perhaps?

     We had posted a way to do this from TOS a long time ago, right
here. If you want it again just holler.
The Cp/m emulator is being passed around on MANY BBSs right here in USA. I
feel that atari made a bigmistake by distributing it free in europe
and not here, as it will be quite impossible to convince people to shell
out $$ for something that you are giving away for free somewhere else,
that they can get a hold of.

***** FLAME ON ****
The following is my opinion on the subject of all these emulators. I know
a lot of people want them.

     It is quite evdident that atari has excellent but extremely limited
resources, to support the ST line. My opinion is that atari should be spending
these resources on getting out new and wonderful things like the TT etc, and
providing better support to existing developers(like Gdos that has
almost become a joke, working copies of rcs, hdx, floating point on Alcyon
V 2.14 was obviously never even tested, maybe even some documentation and
so on....). Let third party developers put out things such as games, emulators
and other addon and end user products.

>>>>>>>>>>>>>>>>>>WARNING>>>>>>>>>>>>>>>>>>>>
Don't spend to much time trying to get my last posting (UniTerm V1.4) to work, probaly it got messed up (by myself, by uuencode.....). I'll try to figure out what happend with those who have already tried!

Simon Poole
K538915@CZHRZU1A.BITNET

P.S. If anybody can stop it getting distributed further, please do!

In article <8610090159.AA09841@ucbvax.Berkeley.EDU> ACS19@UHUPVM1.BITNET (Mike Vederman) writes:
>I received Uniterm, I linked the files together, I uudecoded it, I got the
>exact size it should be... The program does not run correctly. If there is no
>resource, it says no resource, bye bye, otherwise if there is a resource, the
>bee disappears and the program stops, no bombs no nothing, just a green screen
>with uniterm.prg at the top in t he menu bar region.
>
>Anyone else have this problem, or has anyone gotten it to run?
>
>Mike Vederman

I'm afraid I got the same results. All the files came out to be the right size after splicing and uudecoding. Uploaded using xmodem. Uniterm.prg did two different things: First, it loaded, gave the little beginning menu, then asked what buffer size I wanted. No matter which size I chose, it would promptly bomb. Second: I rebooted (just in case it was my ST's fault; my RAM disk has been known to screw up memory), at which point uniterm.prg bombs as soon as it loads. Keyedit.prg loads and appears to run, but I don't really know how to use it well enough to test it (besides, I think I need Uniterm to properly test it, no?).

So, did someone get uniterm to work? Are others having trouble? I'm mailing to Simon, just in case he misses this posting. However, if you do have a working copy, PLEASE do NOT repost it. Let the original poster handle this, so we don't have a repeat of the Hack reposting (where it was properly reposted and then the next day someone comes along and is 'nice' enough to repost it for everyone all over again.)

Thanks,
Maurice T. Franklin

I've had a number of requests for these, so without further ado, here
are both veroff and veron. Extract the lines between the "-- cut here --"s
and place them in "veroff.uue" and "veron.uue", respectively.

```
-- cut here --
begin 644 veroff.prg
M8!H    F         $0                  $_Y    9D*G/SP ($Y!7(\S
:_      $1"\ /SP ($Y!7(]"ITY!     @

end
-- cut here --
begin 644 veron.prg
M8!H    F         $0                  $_Y    9D*G/SP ($Y!7(\S
:_/__   $1"\ /SP ($Y!7(]"ITY!     @

end
-- cut here --
```

For those of you fortunate enough to miss my first crummy attempt at posting
these 2 programs, veroff is a simple little program which turns off the floppy
write verify flag, thereby doubling the floppy write rate. Veron turns the
verify back on, cutting the write rate back to its original (slow) rate.

Keywords: bug spell pascal

I've encountered a somewhat annoying problem with the Spell pgm.
posted some days back by Eric Terrel.. it occasionally wants
to trash the file that is being checked for incorrect
spellings. At one point I backspaced all the way over a word in the
dialog box which asks if the spelling is Ok, add to dictionary or not,
etc., and then selected 'NO'. The program quit, but it seemed to cut
off my file at the point which it had reached (ie. till where it had
checked for incorrect spellings). On other occasions I'm not sure
what I did but the file was chomped. So, it's probably a good idea to
make a copy of the file before running Spell on it (till the bug is
fixed).

Several people complained that part 2 of the Proff repost was truncated.
I didn't notice the problem here, but for those of you who did have trouble,
here is part 2 again, in 2 parts:

```

X.sect 0 1.0 Introduction
X This manual describes PROFF, a formatter based on the FORMAT utility
Xpresented in
X.ul
XSoftware Tools.
X PROFF was produced to provide a powerful formatter that can be used under
Xa variety of microcomputers, thus providing a consistent formatting tool
Xacross environments. PROFF can be used to format memos, reports, form letters
Xand
Xdocuments such as this manual. It can also be configured to mimic
Xother formatting
Xsystems of similar nature.
X This document itself was produced with PROFF, using most of its advanced
features.
XPROFF took care of such things as auto-paragraphing and the production of
Xthe Table of Contents as the manual was being formatted.
X PROFF was developed under a Digital Equipment Corporation Rainbow 100,
Xusing Mark Williams C Compiler for portability reasons. PROFF is
Xavailable under VAX/VMS operating system. PROFF implementations for
XIBM PC and APPLE ][ microcomputers are also underway.
X.st -14
XRainbow, VAX/VMS are trademarks of Digital Equipment Corporation.

```
XUNIX is a trademark of Bell Laboratories.
X.bp
X.cl
X.sect 0 2.0 General Description
X.cl
X.sect 1 2.1 The Input
X The text that is to be formatted by PROFF is typed into an input file
Xusing any text editor. This file contains the text to be formatted
Xas well as PROFF commands.
X Each line in the input file is either a command line or a text line. A
Xcommand line is a line that begins with a period (".").  All other lines are
Xtext lines. The command lines are not printed - they tell PROFF how you want
Xit to format the text that follows. Appendix A summarizes all of the PROFF
Xcommands for a quick reference.
X.sect 2 2.1.1 Text
X Text can be entered into the input file in any format. PROFF removes all extra
Xblanks and tabs between words when operating in fill mode. This means you do
Xnot have to worry about how many words you put on a line, and you can break
Xlines wherever it is convenient to your typing. Note however, that you cannot
Xbreak a word between two lines.
X Blanks and tabs at the beginning of a line are not removed. This is useful
Xfor producing special tables and performing special types of indentation.
XThus, normal text lines should not have any leading tabs or blanks.
X.sect 2 2.1.2 Commands
X A command is a line that starts with a period. Immediately following the
Xperiod is a command name. Some commands accept a numeric quantity or a
Xcharacter string parameter, which must be separated from the command name
Xby a space or a comma. For example, an indent command might appear as follows:
X.save
X.in +5
X.nf
X.nj
X.sp
X|
X|It is to do nothing that the elect exists.
X|.in 5
X|- Oscar Wilde
X|
X.restore
X Assuming that the left margin was at column 1, PROFF would produce the
Xfollowing:
X.save
X.in +5
X.nf
X.nj
X.sp
X.need 4
X|
X|It is to do nothing that the elect exists.
X|     - Oscar Wilde
X|
X.restore
X.sp
```

```
X(In the examples above, as in those following, the vertical line indicates
Xthe left edge of input or the left edge of the printed page).
X The number following the command may be preceeded by a "+" or "-" sign.
XThis plus or minus sign indicates an addition or subtraction of the number
Xto or from the current value for the command. for example, the text:
X.sp
X.save
X.in +5
X.nf
X.nj
X.need 11
X|
X|Nothing to do but work,
X|.in +3
X|Nothing to eat but food,
X|.in -3
X|Nothing to wear but clothes
X|.in +3
X|To keep one from going nude.
X|.in +7
X|-Benjamin King
X|
X.in -5
X.sp
Xwill produce as output:
X.sp
X.in +5
X.need 6
X|
X|Nothing to do but work,
X|   Nothing to eat but food,
X|Nothing to wear but clothes
X|   To keep one from going nude.
X|          -Benjamin King
X|
X.restore
X If a number is not supplied with a command that requires a number, PROFF
Xwill use a default value. The defaults for each command are summarized in
XAppendix A.
X.cl
X.sect 1 2.2 The Output
X The main functions performed by PROFF are
X.ul
Xfilling
Xand
X.ul
Xjustifying.
XA line is
Xfilled by packing as many words onto it as will fit. The line is justified
Xby spacing words evenly between the left and right margins. When PROFF starts,
Xit assumes that the text is to be filled and justified. Of course, when fill
Xand justify are not needed (as in the case of a letter or a table), there are
Xcommands to turn these features off, and back on again, as necessary.
```

```
X When PROFF is in fill mode, it normally strips out extra spaces and tabs
Xbetween words.
X Many PROFF commands cause a
X.ul
Xbreak
Xto occur in the output. This means that the line currently being filled is
Ximmediately output. Any following text goes into a new output line.
X.cl
X.sect 1 2.3 Executing PROFF
X Once a text file is ready for formatting, PROFF is started by typing
Xthe program name, various options, name of the input file and the name
Xof the output file. For example the command
X.sp
X.in +5
XA> proff  -po5 proffman.prf proff.man
X.sp
X.in -5
Xwould produce this document as proff.man, from an input file proffman.prf,
Xshifted right by 5 spaces.
X(The symbol "A>" is CP/M system prompt).
X.cl
X.sect 1 2.4 Bibliographic Notes
X  PROFF wa produced by re-writing the Software Tools Formatter FORMAT.
XSome of the ideas are from Freshwater Institute RUNOFF, NROFF,
XUniversity of Waterloo SCRIPT
Xand other formatters of similar nature. The underlying ideas of the
Xmentioned above formatters may be found in
X.ul
XSoftware Tools
Xby B.W. Kernighan and P.J. Plauger. 1976. (Addison-Wesley, Reading, Mass.).

X.sect 0 3.0 Command Descriptions
X This section describes PROFF commands. Commands specify how the program is
Xto process the text lines in the input file. Lines in the input file that
Xbegin with a period (or the control character selected by the user)
Ximmediately followed by a command name are commands. Any line that begins
Xwith a period and followed by a _# or _! is a comment line and is ignored
Xby PROFF - this allows you to put information in the file that will be neither
Xprocessed nor output by PROFF.
X As described earlier, some of the commands can be followed by "parameters".
XParameters are used in executing a command; for example, in the command
X".sp 3", the parameter "3" tells the formatter to insert 3 blank lines into
Xthe document. The following conventions are used in describing the parameters:
X.sp
X.in +5
X.ti -2
Xo Parameters surrounded by square brackets are optional. If not supplied, PROFF
Xassumes a default value.
X.br
X(e.g. .sp [n])
X.sp
X.ti -2
Xo Parameters surrounded by angle brackets are mandatory. PROFF will display
Xa fatal error message if the parameter is absent. (e.g. .set <variable name>)
X.sp
X.ti -2
Xo Parameters surrounded by squiggly brackets are to be typed exactly as
Xindicated. (e.g. .pn {roman})
X.sp
X.ti -2
Xo A bar character seperating the parameters within brackets indicate an
Xalternative. (e.g. .st [+|-][n] means both .st [+n] and .st [-n])
X.in -5
X In describing the commands, the command is typed exacty as accepted by PROFF
Xwith the associated control character default ("."). If more than one form of
Xthe command is accepted by PROFF, the command names are separated with a
Xbar indicating an alternative.

X.! to avoid the interpretation of the command headers
X.!
X.cchar \
X\!
X\! Variable creation
X\! We use variables to avoid re-typing of multiple options over
X\! and over again. These variable names will be reused in the
X\! appendix to produce a quick referance
X\!
X\set FILL ".fi | .f | .fill"
X\comm FILL
XThe fill command causes a line to be filled with as many words as the right
Xmargin allows. For this purpose, all extra blanks and tabs are removed between
Xwords. Each word is separated with a single blank. PROFF automatically assumes
Xfill mode during the startup.
X\set NOFILL ".nf | .nofill"
X\comm NOFILL
XNo fill discontinues the filling of the text. PROFF simply copies the text
Xto the output. This command may be used to pass tables and other text
Xunaltered through the formatter.
X\set JUST ".ju | .j | .justify"
X\comm JUST
XJustify causes the words on a line to be evenly spaced between the left and
Xthe right margins. Note that lines can be justified only if lines are also
Xbeing filled. PROFF automatically assumes justify mode during the startup.
X\set NOJUST ".nj | .nojustify"
X\comm NOJUST
XNo justify discontinues the text justification.
X\in -5
X\cchar .
X.bp
X.cl
X.sect 1 3.2 Text Formatting
X.in +5
X.cchar \
X\set BREAK ".br | .break"
X\comm BREAK
XBreak causes a break: the current line is printed without justification,
Xand the next word is placed at the beginning of a new line. Note that many
XPROFF commands cause an implicit break.
X\set INDENT ".in | .lm | .leftmargin [+|-][n]"
X\comm INDENT
XIndent causes a break and indents the following lines [n] spaces to the
Xright of the left margin. [n] can be negative to allow beginning a line
Xto the left of the left margin, however, a line cannot begin to the left of
Xcolumn 0. If a plus or minus sign is used with n, then [n] is added or
Xsubtracted to or from the current value.
```

```
X\set TINDENT ".ti | .i | .left [+|-][n]"
X\comm TINDENT
XTemporary indent is identical to the indent command except that it
Xapplies only to the next line of printed text. Thus, the command
X".ti +5" would cause the next line to be printed 5 spaces to the right
Xof those that follow.
X\set SPACETO ".st | .spaceto [-][n]"
X\comm SPACETO
XSpaceto allows spacing to line [n] from the top of the current page.
XIf a negative [n] is specified, than spacing is performed to line [n]
Xfrom the bottom of the page (excluding the footer lines). Thus, footnotes
Xcan be set at a fixed distance from the bottom of the page by a command such
Xas ".st -5".
X\set SPACE ".sp | .s | .skip [n]"
X\comm SPACE
XSpace causes a break and skips [n] lines, except at the top of
Xa page. The space command
Xis dependent on the setting of line spacing.
X\set CENTER ".ce | .center [n | on | off]"
X\comm CENTER
XCenter causes the next [n] lines of text to be centered between the left
Xand right margins. Centering may be started with "on" and terminated with
X"off", in which case all input lines between these commands will be centered.
X\set UNDLINE ".ul | .underline [n | on | off]"
X\comm UNDLINE
XUnderline command causes the text on the next [n] input lines to be underlined
Xwhen printed. If [n] is omitted, only the next line is underlined. This command
Xdoes not cause a break, so words in filled text may be underlined by:
X\sp
X\save
X\cchar .
X.in +5
X.nf
X.need 11
X.sp
X|
X|The "Pay-off" Theory: Only
X|.ul
X|losers
X|believe in luck, horses, horoscopes
X|and
X|.ul
X|lotteries.
X|
X.in -5
X.sp
Xto get
X.in +5
X.sp
X.fi
X|
X.br
X|The "Pay-off" Theory: Only

```
X.ul
Xlosers
Xbelieve in
X.br
X|luck, horses, horoscopes and
X.ul
Xlotteries.
X.br
X|
X.sp
X.restore
XUnderlining may be started with "on" and terminated with "off", similar to
Xthe centering command.
X\set CUNDLINE ".ul | .underline [all | words]"
X\comm CUNDLINE
XThis version of the underline command is used to set the mode of
Xunderlining:
X\sp
X\nap
X\in +5
X\nf
Xall   - underline across all characters,
X        including spaces.
X\br
Xwords - underline words only
X\fi
X\sp
X\in -5
X\ap
X\set BOLD ".bd | .bold [n | on | off]"
X\comm BOLD
XThe bold command causes the text on the next [n] input lines to be highlighted
Xby overstriking. If [n] is omitted, only the next line is highlighted.
XBolding may be started with "on" and terminated with "off" as in the
Xcase of the center and underline commands.
X\set DBO ".db | .dbo | .disablebolding"
X\comm DBO
XTurns the bolding off, all bolding commands are ignored. This feature is
Xuseful for rough drafts.
X\set EBO ".eb | .ebo | .enablebolding"
X\comm EBO
XTurns the bolding feature back on. Bolding is turned on during the PROFF
Xstartup.
X\in -5
X\cchar .
X.bp
X.cl
X.sect 1 3.3 Page Formatting
X.in +5
X.cchar \
X\set LS ".ls | .spc | .spacing [n]"
X\comm LS
XLine spacing is the command to set line spacing. Set n to 1 for single spacing,
```

```
X2 for double spacing etc.
X\set BP ".bp | .pg | .page [n]"
X\comm BP
XThe begin page command causes a break, ends the current page, outputs
Xfooters if required and begins a new page. If [n] is present, the page number
Xis set to [n]. The default action is to number the pages incrementally.
X\set PN ".pn | .pagenumber {roman} | {arabic}"
X\comm PN
XPage number command defines the format of the page number. Uppercase roman
Xnumerals may be obtained with "roman" keyword. To convert the page numbers
Xback to normal, "arabic" is specified. PROFF uses arabic numerals as
Xa default.
X\set NPA ".np | .nopaging"
X\comm NPA
XNo paging disables the pagination. When PROFF is in no paging mode,
X"begin page" (.bp) and "page length" (.pl) commands are ignored. This mode
Xof operation is especially useful for using the proff output with the
Xmulti-column formatter (MC).
X\set PA ".pa | .paging"
X\comm PA
XPaging enables normal page generation. This command starts a
Xnew page and restores the page length to the
Xvalue previous to the ".np" command.
X\set NE ".ne | .need | .tp | .testpage [n]"
X\comm NE
XTest page checks to see whether at least [n] lines remain in the
Xcurrent page. If less than this number of lines remain, printing will resume
Xat the top of a new page. If [n] is missing, it is assumed to be zero.
X\set HE ".he | .header <text>"
X\comm HE
XHeader sets the text to be printed on top of each page. <text> is
Xdivided into sections which are to be left justified, centered and right
Xjustified. To divide <text> into these three parts, the first character is
Xassumed to be a separator. (e.g. /left/center/right/) But any non-alphanumeric
Xcharacter may also be used. The characters "#" and "%" are replaced with the
Xcurrent page number and day/time in the header.
X\set FO ".fo | .footer <text>"
X\comm FO
XFooter is identical to header except that it sets the text to be printed
Xat the bottom of each page.
X\set OHE ".oh <text>"
X\comm OHE
XThe odd header command sets the header for odd pages only.
X\set EHE ".eh <text>"
X\comm EHE
XThe even header command sets the header for even pages only.
X\set OFO ".of <text>"
X\comm OFO
XThe odd footer command sets the footer for odd pages only.
X\set EFO ".ef <text>"
X\comm EFO
XThe even footer command sets the footer for even pages only.
X\in -5
```

```
X\cchar .

X.cl
X.sect 1 3.4 Page Layout
X.ap
X These commands are used to specify where on the page you want the formatted
Xtext to be placed. The general layout of a page is as follows:
X.nap
X.need 30
X.nf
X
X    page offset (.po)                |
X    |                          |
X    V                          |
X    +----+-------------------------------------+----+ -+
X    |    |   top margin (m1) includes header    | |  |
X    +----+-------------------------------------+----+  |
X    |    |        top margin 2 (m2)     | |  |
X    +----+-------------------------------------+----+  |
X    |    |             .           | |  P
X    |    |<-- indent (.in) .           |    |  A
X    |    |             .           |    |  G
X    |    |                T        | |  E
X    |    |                  E           | |
X    |    |                  X               | |  L
X    |    |                  T           | |  E
X    |    |             .           | |  N
X    |    |             right margin (.rm) -->|     |  G
X    |    |             .           |    |  T
X    |    |             .           | |  H
X    |    |             .           |    |  |
X    +----+-------------------------------------+----+  |
X    |    |           bottom margin 3 (m3)       | |  |
X    +----+-------------------------------------+----+  |
X    |    |   bottom margin (m4) includes footer | |  |
X    +----+-------------------------------------+----+ -+
X    |                          |
X    |                          |
X.fi
X.in +5
X.cchar \
X\set PO ".po | .offset [+|-][n]"
X\comm PO
XThe page offset command moves the entire page to the right or left depending on
the
Xspecified value. All indentation is according to the page offset. PROFF
Xassumes a page offset of 0 during the startup. If [n] is specified with a
Xplus or minus, it will be added or subtracted from the current value.
X\set RM ".rm | .rightmargin [+|-][n]"
X\comm RM
XRight Margin sets the position of the last printable character from the
Xleft edge of the page to [n]. Default value for right margin is 65.
XA plus or minus value will be added or subtracted from the current value.
```

XIf [n] is not specified, right margin is set to the default value.
X\set PL ".pl | .ps | .pagesize [n]"
X\comm PL
XPage length is used to set the number of lines that are to be printed
Xon a page including the header and footer lines. After [n] lines are printed,
Xthe paper will advance to the top of next page. The default page length is
X66 lines (11 inches for 6 lines/inch). This command is disabled if nopaging
Xis set.
X\set M1 ".m1 [n]"
X\comm M1
XMargin 1 sets the number of lines (including the header) which will be left at
Xthe top of the page to [n]. The default setting is 3. If [n] is omitted, is
Xset to the default.
X\set M2 ".m2 [n]"
X\comm M2
XMargin 2 sets the number of blank lines between the header and the first
Xline of text. The default setting is 2.
X\set M3 ".m3 [n]"
X\comm M3
XMargin 3 sets the number of blank lines between the footer and the last line
Xof text. The default setting is 2.
X\set M4 ".m4 [n]"
X\comm M4
XMargin 4 sets the number of lines (including the footer) which will be left at
Xthe bottom of the page to [n]. The default setting is 3.
X\in -5
X\cchar .
X.bp
X.cl
X.ap
X.sect 1 3.5 Table of Contents
X This section describes the the commands that are used to generate a table of
Xcontents. Basically, a contents line command is used in every place in
Xthe document where an entry is needed in the table of contents. PROFF
Xstores the text and the page number when it encounters this command.
XAfter the the body of the document is processed, a print contents command
Xdumps the contents table. The contents should be dumped in a new page, with
Xnofill. Page numbering should be disabled if the table of contents is to be
Xused in front of the document.
X.sp
X.in +5
X.ap
X.cchar \
X\set CL ".cl | .contline [<n> <text>]"
X\comm CL
XContents line specifies a line of <text> to be entered into the table of
Xcontents. <n> specifies the level at which the item is to be printed
Xin the table. When the table is printed, each level of entry will be
Xindented by specific number of spaces.
X<text> appears in the output exactly as it appears
Xin the contents line command, except that leading blanks are removed.
XIf no options specified in the contents line, a blank is inserted during
Xthe table output.

```
X\set PC ".pc | .printcont [n]"
X\comm PC
XPrint Contents causes the currently accumulated table of contents to be
Xprinted. If [n] is specified, it is used as the indent value for each
Xlevel.  If [n] is not specified, it is defaulted to 3.
X A contents line at level 0 is as wide as rightmargin-indent. The
Xoutlook of the table of contents may be changed by altering the right
Xmargin and indent values. A typical table of contents may be produced as
Xfollows:
X\in +5
X\nf
X\sp

X.sect 1 3.6 Miscellaneous
X This section describes miscellaneous commands that radically increase the
Xformatting powers of PROFF. With the assistance of variables, PROFF can
Xgenerate form letters and documents with dynamic parts. The ability to save
Xand restore formatter context eliminates the need to remember the exact
Xsettings of the formatter across the document.
X.in +5
X.cchar \
X\set VSET ".vs | .set <variable> [definition]"
X\comm VSET
XSet variable  defines a variable to be later used in the document.
XIf the definition part is left out, PROFF uses the variable name as a prompt
Xand allows the user to define the variable interactively. Variable names cannot
Xstart with a numeric character, and may only contain alphanumeric
Xcharacters. The definition of a variable may not contain any blanks, unless
Xthey are surrounded by double-quotes. To get a double quote within a a quoted
Xdefinition, two double-quotes are used.
X Once the variable is
```

```
Xdefined, it can be used anywhere in the document, including the command
Xline itself. A variable substitution is invoked by a dollar sign (_$). (A
Xliteral _$ is inserted into text using ___$).
XA variable name must be delimited by a non-alphanumeric character within the
Xtext. If the contents of the variable is to be appended to other
Xalphanumeric characters, it must be surrounded by wiggly braces
X("{" and "}"). The following is an example of variable usage:
X\need 12
X\sp
X\nf
X|.nf
X|.vs v1 Murphy
X|_${v1}'s first law:
X|   Nothing is as easy as it looks.
X|_${v1}'s second law:
X|   Everything takes longer than you think.
X|Charley's observation:
X|   Computers were invented by _$v1.
X|
X\sp
XProduces the following:
X\sp
X\need 8
X|
X|Murphy's first law:
X|   Nothing is as easy as it looks.
X|Murphy's second law:
X|   Everything takes longer than you think.
X|Charley's observation:
X|   Computers were invented by Murphy.
X|
X\sp
X\fi
X\set VGET ".vg | .get <variable> <prompt>"
X\comm VGET
XGet variable is the interactive version of variable definition. In this
Xvariant, a prompt string is used to obtain the value of the variable,
Xwhich is typed at the user's terminal. If the prompt string is to
Xcontain blanks, tabs etc., it must be enclosed in double quotes. No quotes
Xare necessary for input text.
X\set VRG ".nr <a-z> [+|-][n]"
X\comm VRG
XNumber register is used to define registers that contain numeric values.
XThere are 26 number registers, named a-z. The command ".nr x n" sets the
Xnumber register "x" to value n; ".nr x +n" increments the number register
Xby n; ".nr x -n" decrements the number register by n. The value of the
Xnumber register x is placed in the text by the appearance of _@nx. A literal
X_@ may be inserted using ___@.
XNumber registers may be used on command lines and anywhere in the text.
X\set CCHAR ".cc | .cchar [char]"
X\comm CCHAR
XControl Character  sets the character that distinguishes PROFF
Xcommands from text to be formatted. As a default, control character is set to
```

```
X(".") period.
XThis character may be changed to something other than a period, either
Xto mimic other formatters or to disallow interpretation of lines beginning
Xwith a period. (This document makes heavy use of the .cc command).
X\set ECHAR ".ec | .echar [char]"
X\comm ECHAR
XEscape Character  sets the character that disallows the
Xinterpretation of spacial characters such as _@ and _$. PROFF uses an
Xunderline ("__") character as a default.
X\set SOU ".so | .source | .include | .require [filename]"
X\comm SOU
XThe source (include) command allows external files to be inserted into the
Xinput file
Xduring the formatting. Using this feature, tables, graphs and other
Xdocuments generated outside PROFF may be included into the document
Xbeing formatted. This feature is also very useful in including a common set
Xof macros during formatting. Include files may be nested inside other
Xinclude files. Currently, PROFF only allows a nested include
Xfiles level of 8. Filename may be enclosed in quotes.
X\set SAVE ".sv | .save"
X\comm SAVE
XThe save command allows the saving of the current formatter context on a
Xpushdown stack. The saved context of the formatter segment (FSECT) includes
Xthe following values and flags:
X\need 14
X\sp
X\nf
X\nap
Xvalues            flags         on   |  off
X------           -----
Xindent       (.in)    fill     (.fi | .nf)
Xright margin (.rm)    justify  (.ju | .nj)
Xoffset       (.po)    paging   (.pa | .np)
Xline spacing (.ls)    number type        (.pn)
Xpage length  (.pl)    bolding       (.eb | .db)
Xmargin values     (.m1)    autoparagraph (.ap | .na)
X        (.m2)
X        (.m3)
X        (.m4)
Xcontrol char (.cc)
Xescape char  (.ec)
X\sp
X\ap
X\fi
X\set RST ".rs | .restore"
X\comm RST
XThe restore command pops the context stack and restores the values and flags
Xas defined above.
X\set LEX ".lx | .lex <command> [equate]"
X\comm LEX
XThe lexical modification command is essentially a permanent replacement of a
Xgiven command. This command is used for changing the command names without
Xresorting to the macro facility. Lex permanently removes the old
```

```
Xcommand name from command tables and replaces it with the new definition.
XIf the equate is not specified, the command  becomes undefined and is
Xno longer recognised by PROFF. The command equate should not contain
Xnon-alphanumeric characters.
X\set APR ".ap | .autoparagraph"
X\comm APR
XThe autoparagraph command turns on the automatic paragraphing feature. If
Xauto-paragraphing is on, every line that starts with a
X\ul
Xblank
Xor a
X\ul
Xtab
Xcharacter starts a new paragraph. A new line is generated (.sp) and
Xthe beginning of the paragraph is indented by five spaces.
XAutoparagraphing is the equivalent of the following commands:
X\in +5
X\nf
X|
X|textextextextext
X|.sp
X|.ti +5
X|textextextextext
X|
X\in -5
X\fi
X\set NAP ".na | nap | .noautoparagraph"
X\comm NAP
XNo Autoparagraph command disables auto-paragraphing.
X\set WRT ".wr | .write <string>"
X\comm WRT
XWrite is a special output command, only to be used to configure printers
Xand other output devices with escape sequences. This command outputs the
Xassociated string as it is encountered, without going through the normal
Xoutput routines of the formatter. Currently, the output string may contain
Xcontrol characters specified as "^<char>", decimal numbers within the range
Xof 1-255, and other characters. Blanks within the string are skipped. Any
Xportion of the string enclosed with double quotes is output as is. To output
Xa double quote, two double quotes must be used within the quoted string.
XFollowing is a typical string to set a Digital La-100 printer to letter
Xquality print mode:
X\sp
X\nf
X\in +5
X|
X|.wr ^["[2z"
X|
X\sp
X\fi
X\in -5
XIn the control string, "^[" is the ASCII equivalent of the Escape (esc)
character.
XFollowing mapping table is used to convert characters starting with a caret
```

```
Xto their binary equivalents: ("|" indicates an alternative)
X\nf
X\nap
X\sp
X\in +5

X.sect 1 3.7 Defining New Commands (Macros)
X In document formatting, it is common to repeat a series of commands at
Xseveral places in the document. PROFF allows you to define a new command
Xthat will replace these repeated commands. This not only saves typing but
Xensures that
X.ul
Xexactly
```

```
Xthe same sequence of commands are applied throughout the document. A new
Xcommand that you define is formally called a
X.ul
Xmacro.
XTo define a macro, you must use the define macro (.de | .define) and
Xend macro (.en) commands.
X.in +5
X.cchar \
X\set DEF ".de | .define <macro name>"
X\comm DEF
XDefine is used to define a <macro name> to which a series of commands to
Xbe assigned. This definition line is followed by any number of PROFF
Xcommands and/or text which define the action that the macro
Xwill subsequently produce. Macros may refer to other macros.
X\set ENM ".en"
X\comm ENM
XEnd macro is the last line in the command definition. You must put in this
Xcommand to finish a currently defined macro. ".en" command should not be
Xre-defined as a macro.
X\in -5
X\sp
XThe example below defines macros ".note" and ".endnote", similar to the
XRUNOFF commands of the same name.
X\in +5
X\nap
X\nf
X\need 20
X\sp
X|
X|.define note
X|.sp
X|.ce
X|NOTE
X|.sp
X|.fi
X|.in +5
X|.rm -5
X|.en
X|
X|.define endnote
X|.sp
X|.nf
X|.in -5
X|.rm +5
X|.en
X|
X\in -5
X\ap
X\fi
X A macro is used like any other PROFF command, control character followed
Ximmediately  by the name of the macro. For example, the above macros
Xmay be used as follows:
X\in +5
```

```
X\nap
X\need 9
X\nf
X\sp
X|
X|.note
X|textextextextextextextextextext
X|               .
X|          .
X|          .
X|.endnote
X|
X\in -5
X\sp
X\fi
XThe following note is generated by the same macros described previously.
X\cc .
X.nap
X.note
XFlap's Law: Any inanimate object, regardless of its position or configuration,
Xmay be expected to perform at any time in a totally unexpected manner for
Xreasons that are either entirely obscure or else completely mysterious.
X.endnote
X.fi
X.cc \
X\ap
XSpecial symbols may be used within a macro definition. These symbols represent
Xthe parameters passed to a macro, delimited by blanks or commas.
XThese symbols are _$0 for macro name, _$1 for the first parameter, _$2 for
Xthe second parameter and so on, up to _$9 for the ninth parameter. Currently,
Xmacro parameters may only contain alphanumerics, no string parameters are
Xpossible. The previous macro "note" may now be defined as follows:
X\in +5
X\nap
X\nf
X\need 20
X\sp
X|
X|.define note
X|.sp
X|.ce
X|_$2 _$3 _$4 _$5 _$6 _$7 _$8 _$9
X|.nr m _$1
X|.sp
X|.fi
X|.in +_$1
X|.rm -_$1
X|.en
X|
X|.define endnote
X|.sp
X|.nf
X|.in -_@nm
```

```
X|.rm +_@nm
X|.en
X|
X\in -5
X\ap
X\fi
X In this version of the "note" and "endnote" macros, the first parameter (_$1)
Xis used to pass the value for indentation and right margin adjustment.
XAll the rest of the macro parameters (_$2 - _$9) are used as the title of
Xthe note. The indent value passed as the first parameter is also saved in the
Xnumber register "m" to communicate it to the "endnote" macro, such that
Xwhen the endnote macro is called, both indent and right margin values are
Xadjusted back to normal. It is possible and may be more useful to use
X".save" and ".restore" commands to accomplish the same task, especially if
Xthe macro alters the current formatting context drastically. The ".note"
Xand ".endnote" macros may be called as follows:
X\in +5
X\nap
X\need 9
X\nf
X\sp
X|
X|.note 5 Asimov's Law of Robotics
X|textextextextextextextextextext
X|              .
X|          .
X|          .
X|.endnote
X|
X\in -5
X\fi
X\ap
X In this usage, the indent value will be adjusted by +5, right margin will
Xbe adjusted by -5, and the title "Asimov's Law of Robotics" will appear
Xcentered above the note.
X\cchar .
X.bp
X.cl
X.sect 0 4.0 Executing PROFF
X The PROFF program  may be invoked with a series of optional parameters and
Xfilenames on the command line. The command synopsis is:
X
XPROFF [+n] [-n] [-v] [-s] [-pon] [-ifile] input [output]
X
XThe square brackets indicate an optional parameter. Interpretation of the
Xparameters is as follows:
X.nap
X.in +10
X.define opt
X.need 5
X.sp
X.ti -5
X.bd
```

```
X$1
X.br
X.en
X.opt +n
XStart the printing of the document at the first page with
Xnumber n.
X.opt -n
XStop printing at the first page numbered higher than n.
X.opt -v
XVerbose mode. PROFF indicates the source files being included into
Xdocument, and produces a summary of the number of textlines read in, the number
Xof lines and actual pages generated. A memory usage summary of internal
Xstorage for macros, stacks and tables is also displayed.
X.opt -s
XStop before each page, including the first one to allow paper
Xadjustment. A prompt is given just before the first page. For each
Xpage thereafter, the terminal bell is rung to indicate that another sheet
Xof paper is needed.
X.opt -pon
XSets the page offset to n. This is equivalent to ".po" command within
Xthe document. It is recommended that -pon option be used instead of
Xembedding the offset value within the document.
X.opt -ifile
XIncludes the given file to the formatted document. This is equivalent to
Xa ".include file" command within the document. This option may be
Xrepeated more than once, -ifile1 -ifile2 etc.
X.opt input
XSpecifies the input file to be formatted. PROFF does not impose any
Xfile extension. The recommended extension is ".PRF".
X.opt output
XSpecifies the output file for the formatted document. If this is omitted,
Xoutput is directed to the user's terminal.
X.in -10
X
XFollowing are some examples of PROFF command lines:
X
X.ti +5
XA>PROFF -v proffman.prf
X
XFormat this document (proffman.prf) in verbose mode, and output the
Xformatted document to the
Xterminal.
X
X.ti +5
XA>PROFF +5 -imacros.pma proffman.prf
X
XFormat this document, include the external file MACROS.PMA, skip the first
Xfour pages and output the formatted document to the terminal.
X
X.ti +5
XA>PROFF -po10 proffman.prf proff.man
X
XFormat this document, shift the entire document by 10 spaces to right and
```

```
Xoutput to a file called proff.man.
X.bp
X.cl
X.sect 0 5.0 Tips on using PROFF
X.ap
X.sect 1 5.1 Care and Feeding of Memory
X PROFF uses a dynamic memory allocation scheme for some of its operations.
XThese are macro definitions, contents lines, variables and save context
Xoperation.
XRunning PROFF under microcomputers with limited memory resources (64k or less)
Xrequire some care in using these commands:
X.list 3
X.item a)
XDo not declare macros that are not needed within the document.
X.item b)
XDo not use comments within macros. Due to delayed evaluation, comments
Xwill also be stored as a part of the macro definition.
X.item c)
XWhere possible, avoid using too much text within macros. It is just as
Xeasy to pass the information during the macro call.
X.item d)
XUse only the shortest form of commands within macros.
X.item e)
XBe brief in contents line text.
X.item f)
XUse short variable names as long as it is not so cryptic as to be confusing.
X.item g)
XAvoid unnecessary blanks within the variable definitions.
X.item h)
XAvoid too many context saves without a corresponding restore. The restore
Xoperation reclaims the memory used for a save.
X.nolist
X Even if the formatter is used with a system of large memory resources,
Xsome of the precautions above are applicable. (Utz's 4th law of Computer
XProgramming: Any given program will eventually expand to fill all the
Xavailable memory.) Using the -v option under memory-restricted systems
Xmay be useful in determining the memory usage.
X
X.sect 1 5.2 Formatting without fuss
X PROFF, using its default settings, may provide reasonably formatted output
Xin many situations.
XAs an example, examine the document PROFF.TUT. This document does not use
XANY formatting commands. All formatting is done with the default settings.
X
X.sect 1 5.3 Variables within macros
X Variable expansions may be performed within the macros. Typically, one
Xof the parameters of the macro is assumed to be a variable, which is expanded
Xonly after the macro is used. Thus:
X.in +5
X.nf
X
X|
X|.define xx
```

```
X|.ce
X|_$_$1
X|.cl _$_$1
X|.en
X|
X
X.in -5
X.fi
XThe macro xx assumes the first parameter to be a variable, which is
Xcentered on the page, and also entered in the table of contents.
XNote the usage of "_$_$1". The lines within a macro are scanned from
Xright to left for parameter expansion. Thus, "_$1" is expanded first,
Xresulting in "_$<first parameter>". This is later expanded as a variable.
X
X.bp
X.cl
X.sect 0 6.0 Example macros
X
X.nf
X.in +5
X.cc \
X.!
X.! macros to create a point-form lists.
X.! note the use of number registers within
X.! the macros.
X.!------------
X.define list
X.nr a _$1
X.in _$1
X.en
X.!------------
X.define item
X.sp
X.ti -_@na
X_$1
X.en

X.en
X.!------------
X
X\in -5
X\fi
XThe "list" macro is used to generate point-form lists. The first parameter
Xis an indent value, size of point-str + 1. A typical usage may be as
Xfollows:
X\need 16
X\in +5
X
X\nf
X|
```

```
X|Project work involves:
X|.sp
X|.list 3     { size-of-point-str + 1 }
X|.item a)         { "a)" is the point-str }
X|choosing a topic
X|.item b)
X|defining the topic
X|.item c)
X|research
X|.item d)
X|organizing the notes
X|{etc.}
X|.nolist     { readjusts the indent  }
X|
X\in -5
X
XThe above usage will produce the following:
X\need 12
X\in +5
X
X|
X|Project work involves:
X|
X|a) choosing a topic
X|
X|b) defining the topic
X|
X|c) research
X|
X|d) organizing the notes
X|
X
X\in -5
X\fi
XThe point-form recommendations under section 5.1 (Care and Feeding of
XMemory) were generated with the same set of macros described above.
X\cc .

Keywords: The real story (console I/O in GEMDOS)

The real culprit is what I would refer to as a "semi-circular" buffer
in GEMDOS's character I/O routines. When you read with Cconin(), you
must read ALL the characters that are available before using Cconout()
or Cconws(). If you don't, the buffer will overflow and cause a
crash. (The program at the end of this posting demonstrates the
problem quite dramatically).

The BIOS has no such problem. My philosophy is (and always has
been) to avoid the GEMDOS console, aux and printer functions, and
go directly to the BIOS.

```
>  /*

Keywords: Atari C-source C++ identifiers Megamax object-oriented
Summary: Megamax uses 10 chars of any length identifier
Xref: mnetor net.lang.c++:365 net.micro.atari16:2449

Regarding the need for a C compiler that would handle long
identifiers, y'all might not know that Megamax recognizes
the first 10 chars, and allows very long total length.
That may still not be enough for C++ - I dunno.
(and you still need to get that C++ preprocessor...)

BTW: I devised a method to do object-oriented programming in C.
Not fancy but simple, and you get inheritance and even late binding
of sorts with high efficiency (about 100 microSecs for a typical
invocation of a method). If anybody is interested let me know.

Since so many people have asked what does/doesn't work under magic sac, I am going to post the following rather than waiting until I have my own list together. I will follow this up with my list, as soon as I have one. (:-)

This list is abstracted from the readme which comes with version 2 of Magic Sac. I have not edited what's here, I have only removed portions of the readme which don't have to do with the list. I have not run most of this stuff myself, and can't vouch for it. Right now, the only thing I can vouch for is FreeTerm 1.8, which definitely does work.

Marty

KNOWN BUGS:

MacWrite: (2.2 / 4.5)

MacWrite crashes the system. We are working hard to fix this. We are most of the way there (for instance, it prints), however, the authors did not follow developer's guidelines, and it's tricky. We don't think holding up this release for the fix is a good idea.

Switcher:

Because so many people want Switcher, we are attempting to work around it some direct hardware references in it which otherwise make it fail. Look for it fairly soon.

Finder 1.1g

Finder 1.1g actually may work better for you than 4.1; 4.1 seems to have some bad effects on application software. As an example, Zork III works under 1.1.g, but not under 4.1.

There is one known bug in 1.1g: if you open the trashcan, then click on the menu bar, the system dies. Fix: don't do this. This bug does not apply to 1.0 or 4.1.

****

List of Works / Doesn't Work Software

Revision 2.00, 10/1/86

Some of the "Works" software has been extensively tested; others, just basically booted and briefly tested. However, we feel the list may be helpful to you nonetheless.

Please help us keep it up to date and to expand it.

We will periodically upload it to Compuserve and BIX.

WORKS

Apple Finder 1.0
Apple Finder 1.1g
Apple Finder 4.1 (note: may fail on 128K size inconsistently, see note)
Apple MacPaint 1.5 (note: 1.3 has a bug in FatBits, fixed in 1.5)
Apple Edit Oct. 22/1984
Apple MacDraw 1.9
Apple MacProject 1.0
Apple REDIT (6/86 update)
Apple Disk Utility (5/85 update)

Aldus: Pagemaker (only a non-protected version, not yet available)

Arrays / Continental Software: The Home Accountant V. 1.03

Assimilation: RAMDISK program.

Chang Labs: R&R Ledger system

Desktop Software: 1st Base V1.01

Dreams of the Phoenix: Freeterm 1.6, 1.8. NOTE: Use these to modem with.

Bishop Graphics: Quik-Circuit (PC Design package)

Haba Systems: Habaword 1.2, 1.3, 1.4 (very nice word processor)

Infocom: Zork III. Note: works well under Finder 1.0, not so well under 4.1.

Main Street Software: Main Street Filer V. 1.1

Keywords: also cannot get it to work - three bombs

<<<<<>>>>>

  I would like to throw in my additional note that when I try to run
it on a TOS in ROM 520 I get 3 bombs, but with TOS in RAM I get >5
mushroom clouds. I checked the file sizes and the decoding (the
keyboard mapping program that came with it works fine).
  Maybe a re-posting would be in order? A fix to the uuencoded
files?

              Bob

Ask

> Challenge: can anybody devise a way to stop a running program that does
> not do any I/O (i.e. does not respond to ctrl-C), but WITHOUT rebooting!?
> (I currently embed calls to keybrk() here and there in my loops, where
> keybrk() is just a call to GEMDOS to see if ctrl-C was pressed, and an exit()
> if it was... - that works but is ugly!) - I would like some program that
> responds to an interrupt (say the alt-Help) and stops the currently running
> application, in a clean way (no crashes or reboots, ability to do it
> repeatedly in a session). I would like this ditty to be a separate program
> that you run once and then it sits resident in RAM. I have tried such
> a thing, with the interrupt handler doing an RTE to itself and then calling
> gemdos(0) - but I get mysterious crashes after a few uses! Any ideas?
>
> - Moshe Braner

and thou shall receive:

WATCHER is another goodie from the Happy-Computer PD-Disk (remember MONST).
It should work as follows:
If your program gets stuck in an endless loop
     then press 3 times CTRL-B and once CTRL-C

The executable has been UUENCODED on the ST. The source is for assembly
language adventurers.

As an additional bonus I've thrown in TBUG.PRG. Place multiple copies of it
into the AUTO folder of your best friend and watch his/her eyes fall out.
Have fun, but don't flame me!

Summary:

[]

I've ported a C program to draw Julia sets (skins of fractal dragons) from
a vax here at U of W to my 1040st. It uses recursion, and on the vax this
goes about 500 to 3000 levels deep, depending on what values i feed to the
program. Unfortunately, when i moved it to my ST, it died after about 170
nested recursive calls. Further experimentation indicated that only about
7800 bytes is available for local variables, parameters, and return addresses
on the stack from megamax C. The manual claims that if you want more stack
space, you can modify the STACKSIZE constant in \megamax\init.c; I changed it
to 64000 bytes and a few other values, but to no avail.
Help!
Does anyone out there know how to make the stack as big as you want?
It seems to me that some other code internal to megamax didn't realize
i'd changed STACKSIZE from the original 8K, if that's any help.

     Thanks in advance,
          Camille.

Could someone please mail me the documentation for uniterm. I picked
up the latest posting, but hadn't used it before.

Thanks....

Tony Andrews

Sorry, false alarm...my last posting about the cause of the problems
with UniTerm wasn't true...it was just a REXX program playing tricks
on me..(back to looking for that error..).
           Simon Poole

Well, I just got Uniterm 1.5 from Simon Poole, and I can say that this new
version does work, and did uudecode just fine.

I haven't tested out all the functions yet, but it seems OK.

Mike

p.s. can someone send me uEmacs part 1, I also did not receive it.

I accidentily threw away the uuencoded version of MONST posted a while ago.
Since I have discovered how to successfully uudecode all files now, could
someone please send me the file(s). I have the docs that were just posted.
Thanks,

Mike

P.S. Look for a posting of a terminal program I am working on, coming to
a computer near you. Also, look for some nice utilities.

# 2. Save the resulting text in a file.
# 3. Execute the file with /bin/sh (not csh) to create:
#    expl
#    emacs.uue
# This archive created: Mon Oct  6 10:06:23 1986
# By:    D'arc Angel (The Houses of the Holy)
export PATH; PATH=/bin:/usr/bin:$PATH
echo shar: "extracting 'expl'" '(1569 characters)'
if test -f 'expl'
then
     echo shar: "will not over-write existing file 'expl'"
else
sed 's/^ X//' << \SHAR_EOF > 'expl'
     XThe file emacs.uue contains uuencoded version of Dan Lawrence's MicroEmacs
     X3.7i ported for the Atari ST. It supports both b/w and color monitors by
     Xadding three new modes for the four screen resolutions as follows:
     X
     Xmode    monitor type  screen resolution  colors
     X------  ------------- ------------------ ----------------
     XHIREZ   black & white 40 lines x 80 cols none
     XMEDREZ  black & white 25 lines x 80 cols none
     XMEDREZ  color         25 lines x 80 cols black,red,green,yellow
     XLOREZ   color         25 lines x 40 cols black,red,green,yellow,
     X                           blue,magenta,cyan,white
     X
     Xmodes may be set by the sequence ^xm (cntrl-x m) and typing the mode as
     Xshown. To bypass the problem of recalculating window sizes when multiple
     Xwindows are present during a resolution change, the current window is
     Xalways made the only window after the change.
     X
     XThere is still one MAJOR ugly with this port; you can't change the
     Xdefault colors, as soon as i can come up with a scheme that will work
     Xin both interactive and emacs.rc mode i'll implement it (think before
     Xyou post, it ain't as straight forward as it looks in emacs.rc mode)
     X
     Xalso the cursor will be restored if it was present when emacs was invoked
     X(e.g. from the Beckemeyer shell); writting the file out is still a PIG!!!
     Xand for reasons known only to himself Dan changed the spelling of
     X'begining' to 'beginning' please change your emacs.rc files accordingly.
     X
     Xsources may be requested from Dan Lawrence (inph4!itivax!duncan!lawrence)
     Xplease don't ask me since I am always a release behind Dan.
     X
     Xas usual bugs suggestions etc. are always appreciated
     X

Does anyone have an assembler i could send them a disk for?

And where does one get hold of Magic sac?

Please reply to glk309@uiucuxa

                    Thanks in advance

                         -E. C. Spieu!

~~~~~~~~~~~~~~~\ lineater, \~~~~~~~~~~~~~~~~~~~~

here's a cute bug in megamax C:

```
int c;

     while((c = getchar()) != EOF) {
.
.
.
     }
```

works fine but:

```
unsigned char c;

     while((c = getchar()) != EOF) {
```
~~~~~~~~~~~~~~~

```
.
.
.
     }
```

loops infinately, the problem is that megamax generates the
following code:

```
     AND  #0xff,D0  ;D0 has the result of getchar
     CMP  #-1,D0        ;ooppsss should be CMP.B
```

ah well

Hi,

Starting yesterday, I receive two copies of every message I send to the group,
and I sometimes also receive two copies from other people. It's just a minor
annoyance for me (I can easily delete double copies) but I don't want fellow
netters hacked off at me for "cluttering the net."

Just whatever you do, don't remove me entirely from the group: it's my only source of tech info for the ST.

Keep up the good (interesting, useful) work!

Jim Moore

How available is the Magic Sac?  Can I order one directly from
the company?   If so, can someone who has one supply me with the
address and phone number I should call to order one, or get on a
waiting list for one?

with checkbook in hand,
   Mike Cohan

Here is a real Gem of an utility, from CompuServe. It will let you
compile resources created with RCS (any version) right into your program.
No more hunting for the '.RSC' file. Please use it in your code.
It will help others who like to run programs from different directories,
it helps alleviate the dynamic memory allocation probelm somewhat as you don't
need rsrc_load() anymore, and it will help people like me who can never seem
to find the '.rsc' file when needed.

enjoy,

X
X/*************************************************************************\
X*   rcsfix.doc
X*
X*  RSCFIX.C -- A resource fixer for code-resident resources.
X*
X*  RSCFIX.C  contains  a set of routines to prepare  a  code-resident
```

```
X*  resource  for use.   It was derived from STCREATE.C,  found in the
X*  RSCREATE  folder  on  the Resource Disk supplied  with  the  Atari
X*  Developer's Kit.
X*
X*  The  routines are driven by a main routine,  rsc_fix(),  which you
X*  call  during your program initialization to prepare the  resource.
X*  The  routines perform 2 distinct functions on the  resource.   The
X*  first is to change all the offsets,  generated by RSC,  to address
X*  pointers.   The  second  function  is  to change  all  the  object
X*  rectangle  coordinates  and  sizes  from  characters  to   pixels,
X*  according to the current screen resolution.
X*
X*  First  get  the download the file RSCFIX.C and put  it  with  your
X*  header  files. (e.g.  on  the compiler disk with  ALCYON,  in  the
X*  HEADERS  folder with Megamax,  in the INCLUDE folder with  Micro-C
X*  Shell and Mark Williams C, etc.)
X*
X*  Next,  create  the  C source file using RCS or RCS2.   To do this,
X*  run  the RCS program,  Open your resource file,  select the Output
X*  option  from the Global menu,  select '.H' and '.C' ('.C' & '.RSH'
X*  for RCS2),  click on OK,  and Close your resource.   Put the these
X*  files with your source file(s).
X*
X*  Then,  modify  your source file to include the resource's C source
X*  and header files and 'RSCFIX.C'.   Change your call to rsrc_load()
X*  to  rsc_fix().   Change  your call to rsrc_gaddr to load the  tree
X*  pointer from the rs_trindex[] array.
X*
X*  Limitations:   The  'adj' macro takes care of objects that are not
X*  character  aligned but seems to have trouble when the root  object
X*  of a tree is NOT character aligned.   Just make sure all your root
X*  objects  are  character  aligned  and  you  should  not  have  any
X*  problems.
X*
X*  The following code fragment illustrates the use of rsc_fix().
X*
X*  #include <obdefs.h>
X*  #include <gemdefs.h>
X*  .
X*  .
X*  .
X*  #ifndef BYTE                  / Take care of 'portability' /
X*  #define BYTE char             / macros in the '.RSH' file. /
X*  #define WORD int
X*  #define LONG long
X*  #endif
X*
X*  #include "resource.h"         / The header file from RSC   /
X*  #include "resource.rsh"       / The C source file from RSC /
X*
X*  OBJECT *tree;                 / Pointer to an object tree  /
X*  .
X*  .
```

```
X*  / global declarations /
X*  .
X*  .
X*  #include <rscfix.c>           / Code to fixup resource     /
X*
X*  void    sort(v,n)
X*  char    *v[];
X*  int     n;
X*          {
X*          .
X*          .
X*          }
X*  .
X*  .
X*  .
X*  void    do_form( rsc_tree, exit_obj )
X*  int     rsc_tree;
X*  int     exit_obj;
X*          {
X*          int     xdial, ydial, wdial, hdial;

Marty:

Could you post the list of software that the Magic Sac
works with? Also, was this called the MacCartridge at one time?
and is it the one done by David Small?

Always a question...

Aloha,

I have in my office the new issue of Atari Explorer. Newsstands should
be receiving them already, as should the existing subscribers.

As promised in the editorial, the next issue will be out in a little less
than 2 months.

So, Ive just got the part 5 of my posting of UniTerm back from info-atari16.
No wonder it didn't work!!
Somebody is changing [(left square bracket) to (backslash) and
] (right square bracket) to ! (exclamation mark).

Find that computer and shoot it....
Until then, will everybody refrain from posting uuencoded binarys!!!!!!

I guess the hardware junkies who post to every group under the sun have
decided to ignore our flames. Does anyone have a program to read news
which will automatically delete any reference to 68xxx chips that appear
in any group other than net.micro.68k? Either that, or let's set up a
moderated group that includes everything but the chip dip.

You can survive with C++ and only 31 significant characters in your C compiler and linker. Don't try with less. If you have only 31 significant characters complain (politely) to your compiler and linker supplier. Such complaints have been known to have a positive effect - eventually.

> (and you still need to get that C++ preprocessor...)

The C++ translator, known as cfront, is a preprocessor only in the sense that the UNIX C compiler is a preprocessor for an assembler. Calling it a preprocessor is misleading.

Probably the best way of thinking of cfront is as the first pass in a classical two pass compiler: cfront does a complete syntax check, a complete type check, expands inline functions, adds temporary variables where necessary, makes implicit initializations explicit, makes implicit type coercions explicit, etc.; finally it produces an intermediate form of the program to be read by the second pass. Using C as the intermediate form is very useful for portability.

Any error messages produced by a C compiler while processing cfront output is considered a bug in either cfront or the C compiler. By definition cfront does not rely on the C compiler for anything but code generation.

This made me curious about what the cost of a C++ virtual function call really is so I ran this example on a VAX11/750:

```
struct s {
     virtual f();
};

s::f() {}

main() {
     s* p = new s;

     for (int i = 100000; 0<i; i--) p->f();
}
```

It took 4 seconds; that is, about 4 microseconds per iteration.
For comparison I also ran

```
f() {}
```

```
main() {
     for (int i = 100000; 0<i; i--) f();
}
```

It took 3 seconds; that is, about 3 microseconds per iteration.
Finally I ran:

```
main() {
     for (int i = 100000; 0<i; i--) ;
}
```

It took .5 second. All timings are averages of several several runs.

These times were a bit disappointing in that I could measure the difference between a virtual function call and a ``normal'' function call but, I think, not bad. You can do a fair bit of work with a million function calls.

Maybe I ought to mention that with virtual functions there is no difference between calling one virtual function twice compared with calling two virtual functions once (many schemes for method lookup involves a slow first call followed by fast subsequent calls so that simply invoking the same method a million times would be a too easy test). No trickery, inlining, optimizing, etc. was involved.

Does anyone know of a program that will convert the ST keyboard into a Dvorak keyboard? I seem to recall something mentioned about that here, before.
Better yet, is there any way to get an Atari with a Dvorak keyboard?

Thanks,

CL

  Has anyone seen a utility that will extract a "shar" file into it's separate files on a ST? Perhaps the line editor with the Micro C shell is close enough to do the job. I was also curious if anyone knows of a source for raw 3.5" double sided drives. I'd like to upgrade to 2 DS drives but I don't want to spend $500. Putting a 5.25" drive on the ST was so easy I'm sure that putting a pair of 3.5" drives won't be much of a problem either.

This is a feature of some versions of the *BITNET* software running on IBM
systems. The problem being the the EBCDIC code never has had consistant
translations between the characters on printers, keypunches, displays and

their ascii equivalents. This resultes in a 'correct' translation and a
'useful' translation. YEECH!!!

If you are using a IBM system, you are screwed. If you're on a ascii flavor
unix system, then you can arrange to have articles posted locally uucp'ed to
a backbone or other non-ibm site. Many sites will accept postings through
rnews or rnmail even though they can't accomodate extra feeds.

The alternative is to send a diskette to some cooperative soul with better
connections or upload your program to the Atari BBS and just mention that
it's there...

 That is definitely an IBM computer that is doing it. EBCDIC does not
have '[' and ']' in the character set. Don't shoot
the computer, shoot IBM. Now we know what is at the root of all these
problems. BRAIN DAMAGED IBM MACHINES (once again!!).

 May i make a suggestion. Lets drop UUENCODE and adopt BinHex. There is a

good reason why people in the Mac world use it. Even IBM computers can handle the characters 'A'...'F'. If there is enough interest i will post the source for BinHex here.

Not having uudecode for the ST, I have been doing the decode on Unix and then Kermitting (?) the result to the ST. So far, none of my programs has worked. Should it? Is there anything inherently wrong with this approach?

I have tried this on Uniterm (which appears to have other problems anyway, judging by the news going past), arc (which I would really like to have), and Mandlbox.

Help.   (:-(As usual, please reply by mail.

Some comments on the recent postings (mostly failure stories):

1. I downloaded ARC and uudecoded it on my Atari. I think the uudecoded version works correctly. At least it seemed to list, verbose-list, and extract ALITE without bombing out. However:

2. I downloaded ALITE and uudecoded it on my Atari. I then used ARC to extract ALITE from archive. All the filelengths matched what was expected. However, ALITE did *not* work. It just hung the machine. Anyone managed to get ALITE to work?

3. Our site still hasn't received part 1 of uEMACS 3.7i. I notice others with the same complaint, so will someone please repost it? Or at least send me a copy?

4. Our copy of UNITERM 1.4 doesn't work. Looks like the same error others are reporting. Anyone managed to get UNITERM to work?

I've been waiting for these programs with bated breath, so if you have any clues, please help! In particular, do tell me if you managed to get these programs to work; maybe send me your copy if you have a working version.

Thanx -- Ashwin Ram.

Interesting,

in Germany Atari has dropped the prices for the 1040 last week (Oct 1st)
from former DM 3298,-- ($ 1650,--) to DM 2498,-- ($ 1250,--). The rumor was
that the 1040 was sold only very bad. The new price is about DM 400,--
($ 200) below a 520 with same specs only in more parts and with separate
power supplies. The price for 520 and 260 has NOT been dropped!!!

>
> ah well

I pulled out my copy of the C bible (K&R) and I found the following quote:

   On a machine which does not do sign extension, c is always positive
   because it is a char, yet EOF is negative. As a result, the test always fails
   to avoid this, we have been careful to use int instead of char for any
   variable which holds a value returned by getchar.

   The real reason for using int instead of char is not related to any
   questions of possible sign extension. It is simply that getchar must return
   all possible characters (so that it can be used to read arbitrary input) and,
   addition, a distinct EOF value. Thus its value cannot be represented as a
   char, but must instead be stored as an int.   (page 40)

This brings us to EOF. If EOF is defined in such a way that it is
represented as an integer, then you go pp 183-184 to find that "A
character or a short integer may be used wherever an integer may
be used. In all cases the value is converted to an integer." The
section on unsigned is a little vague as it only addresses integers

and their conversion to long, but the basic principle is to pad left with
zeros.
Im no expert on C; Ive not used it for that long but I think that the bug
is in the example, not the compiler.
                                                                -Steve

>with UNITERM.PRG written at the top. Any ideas?

     I decoded it last night and it didn't run. The ending of the
encode looks a bit funny to me. The last line didn't start with
an 'M' like the rest. I haven't looked over my UUDECODE source
lately, but I wonder if it has any error checking at all? If not,
then the last line (or more) could have been trash. My decoded
object ended up a bit bigger than the original at that.

Cheers! -- Jim O.

Camile,

After you changed the init.c program and compiled it, are you sure the new
verion was used when you linked your program? To use a new init you must
do one of two things:

1) Specify init.o on the command line to the linker along with the other

.o's for your program. This will tell the linker that you want to override the init.o found in the system library.

2) Replace the init.o in the 'syslib' library with your altered one. Now the altered one will be used automatically.

If you already tried these two methods and it still doesn't work, then I'm not sure what the problem is. If this is the case, let me know the answer when you find out! :)

Does anyone know of a PD time and date program that works with the mono monitor? Right now I have the Time/Date 1.0 by Matthew R. Singer dated 10/25/85. Sometimes after I enter the date it resets the computer and prompts again (I have it in my AUTO folder). Any comments/uuencoded prgs (!!!) are encouraged.

Jim
Batteries Included has made BICLOCK.PRG available from Compuserve. It is also included as part of THUNDER V1.3.. I tried The Compuserve version with the Mono Monitor in an AUTO folder and it got hung up. However, The version with THUNDER works fine. It looks like there is more to the AUTO folder than meets the eye!!!

Three questions regarding MicroEmacs 3.7i:

     (1) What commands will the Parameters Box accept when opening the program?

     (2) In MicroEmacs 3.6, the command ^X C opened a path to an MS-DOSlike command processor called COMMAND.TOS. In the new version, trying to invoke the command processor produces the warning, "Not in TOS." Is this easily fixable?

     (3) Is it possible to store default settings for mode, fill column, etc. in an init file (perhaps the rc file)?

Thanks,

I guess I'll add my two cents to the ARC/ALITE saga. I was able to
successfully unpackage ARC and ALITE, uudecode and download to my ST.
Then I ran ARC.TTP on ALITE.ARC and got the proper files. When I
double-clicked on ALITE.PRG I saw the introductory slide with instruc-
tions on how to continue and heard some beautiful Bach-like music.
However, when I tried to continue (with the "N" or "S" commands)
nothing happened. So my question is, does 1ALITE.PIC contain only
the intro slide or is there more? The music was impressive, but I
expected to see more. The only possible problem I noticed was that
Xmodem told me it was transferring 192 blocks for ALITE.ARC, but 193
were actually transferred. Any suggestions Rich, or anyone else???

>it before letting it out again. It will be distributed *soon* on
>Compuserve, on the Atari BSS, and to dealers. [Not on usenet, though,
>for obvious reasons.]

What reasons, pardon. We developers here in Europe would be also very
interested in such updates, because the communication between Atari (US)
and for instance Atari (Germany) is not even poor, it is lousy.
We get the update here always half a year later or even longer.
Last week I heard, that the official version of GDOS is published to
the developers in the US over a month ago, and here in Germany:
The German subsidary even doesn't know, that something like that exists,

though Atari himself always proudly tells, that the German market is one of the best for the ST series.
But the very best is:
About a year ago I was flamed very much by members of Atari (US) and other people, because I have posted the CP/M-Emulator (here in Germany public domain) to usenet. Now neil@atari says that Atari (US) will put this emulator also into the public domain --- and now he asks us kids here in Europe, how to put the utilities onto CP/M disks. You must decide at Atari: if you want to take, you also must give. Some comment on this from Atari (Neil, Landon) would be very nice.

Greetings

Having recently bought a CZ-101 and hooked it to my ST, I'm in a "transport of musical delight"! However, the documentation that comes with the synth is quite awful, and lacks certain information. Since the CZ-101 is supposed to be a hot seller among ST fans, I'm hoping someone out there can answer these questions:

1) For "system exclusive" MIDI messages, what is Casio's manufacturer ID code?

2) Also for "system exclusive" MIDI messages, the manual lists the various names of messages that the synth responds to, but not their encodings. Does anyone know the exact sequence of bytes and their values?

By the way, if you're looking for a good book on MIDI, one has finally come out. "MIDI for Musicians", by Craig Anderton, is a VERY well-written and clear presentation of MIDI and how it works. I recommend it! (standard disclaimer here)

Thanks for your time!

Could someone give me some ideas about what to try to salvage my memory
upgrade? I have a 520 with the rev C board. I followed the instructions
for the upgrade carefully and am reasonably confident that I have not made
any mistakes. I removed the capacitors, piggybacked the new ram chips,
reinstalledthe capacitors, ran the new cas low and cas high buses and the
new ras bus, installed the 68 ohm resstors in series with those lines to
the mmu. The next part of the upgrade called for the cutting of the old
cas and ras lines to the original memory bank and then remaking the
contacts with a 68 ohm resistor in series. On the rev C board, atari has
already cut these traces and installed 68 ohm resistors on the cas lines
at the ram chips. kkSo I just cut the ras line and added the 68 ohm resistor,
thankig atari for making my job a little easier. I checked all resistances
from the mmu to the appropriate bus and all looked great. When I rebooted
my 520 everything looked fine except the new memory was not there! So I
used basic to check things out. I have memory that I can write to from
$80000 to $9FFFF. All bits in high and low addresses work swell. From

$A0000 on up I get $48 and $80 in odd and even (or even and odd) addresses
So it appears that the computer is willing to read and write from the low
128k or the addition but not above that. All of the base 512k is there.
Could someone please send me some ideas such as how the mmu recognizes whether
the second bank is made out of 64k, 25k or 1M drams? Thanks very much.

>
> ...I decoded it [UNITERM] last night and it didn't run. The ending of the
>encode looks a bit funny to me. The last line didn't start with
>an 'M' like the rest....

    The last (nonblank) line of UUENCODEd files doesn't have to start with an
'M'; the ASCII code of the first character in each line is 32 + the number of
bytes that the line will decode to (so 'M' = 45 bytes, after decoding). Thus,
if the total number of bytes in the original file is not a multiple of 45,
the last nonblank line will be shorter than normal and will start with some
character other than an 'M'. Here's an example: I took the following 2 lines
(93 bytes)

This is a test file to demonstrate UUENCODE.
This is the second, and last, line of the file.

and UUENCODEd them; the result is

```
begin 644 file
M5&AI<R!I<R!A('1E<W0@9FEL92!T;R!D96UO;G-T<F%T92!5545.0T]$12X*
M5&AI<R!I<R!T:&4@<V5C;VYD+"!A;F0@;&%S="P@;&EN92!O9B!T:&4@9FEL
#92X*
```

end

. The '#' in the last line indicates that after the 90 bytes contained in the first two lines, there are 3 bytes left over.

Thanks Neil. I just got the new issue in the mail the other day. It really good!
Now I know why it takes you a while to answer our questions.
How about giving some of us Net users a tours of Atari??

Summary: possible solution

I hear all these complaints that most C's only support 8-character
identifiers, and the C++ preprocessor *needs* thirty-two.

Say we use only 7-character letters-only identifiers.
26^7 = 8 031 810 176.
Seeing as how any C++ preprocessor is unlikely to produce over 8 billion
different identifiers, is there a good reason why a little filter couldn't
be inserted between C++'s output and C's input to shrink the size of these
huge identifiers to a manageable size.
Sure, it's slow; we've got a 8 MHz 68000. Sure, it's a kludge; it works!
(I hope)

Camille

Subject: This is getting ridiculous

Over the period Thursday-Sunday, I received about 20000 lines of mail from
the info-atari16 mailing list, most of it uuencoded programs that I neither
needed nor wanted. I don't enjoy having to wade through all this junk,
especially when I have a program that automatically concatenates all of the
atari messages into one file. There is no way to differentiate between a
1500 line program and a regular message. It would be nice if one of the
following could be done:
a) A separate list for programs is created
b) we adopt some special Subject: line to differentiate programs
c) we stop postingg such long things over the net

I don't enjoy getting 9000 lines of proff or whatever and then hearing in
another message that the whole pile doesn't work, and I'm sure the people
who run the system here don't like having my reader jammed like this.

Question on uE3.7i. What does the command 'add-global-mode' do? I had assumed
this was to change the text color, but nothing happens. Also note that mode
blue is no longer defined.

This is my first ever posting!

Has anyone been able to get hardware flow control to work
on the 1040ST?

Code sample 'C' or 'OSS PASCAL' would be appreciated.

Thanks -

Can someone tell me how to define a macro in a emacs.rc file for the
recently posted emacs 3.7i? I've tried:

```
start-macro
ksdf;lksdf sdksdflk sdf  ;; <-- text to insert...
end-macro
universal-argument
1
store-macro
```

unfortunately it complains about an unknown function...

BTW, this is a great implementation! the cursor follows the mouse, 40 lines
in mono, yippee!

=-=
No problem is so formidable that you can't just walk away from it.

This from Personal Computing, Oct. '86:

10 Unexpected Personal Computing Flops
or Under-Achievers

1) PCjr
2) Lisa
3) IBM Portable
4) Jazz
5) Apple III
6) Tandy 2000
7) DEC Rainbow
8) VisiON
9) Amiga
10) Ovation

Does this tell us something? Does anyone know (preferable not
connected with Atari or Commodore) what the *actual* figures
are for machines (ST vs. Amiga) are thru 3rd quarter '86?

I shall change my name to George... curious George, that is.

Aloha,

Jonathan Spangler

sed 's/^x//' << \SHAR_EOF > readme
xScribe-->Proff v. 2
x
xThis is an update of my preliminary posting and includes a number of
xenhancements.  The program now supports "devices" via the @device() command.
xThere is an array of structures in device.c that can be edited to add more
xdevices (only Brother/Diablo daisy wheel printers are fully supported).  The
xfile var.c includes the dynamic memory allocator, lookup, and installation
xfor the string, value, and index commands.  The chapter and section commands
xalso use the variable table maintained by the routines in var.c.
x
xTwo new commands in device.c allow you to modify the pitch and line height
xon your printer, assuming it has minimum horizontal and vertical movement
xstrings.  They take integers as arguments in the style of WordStar (i.e.
x@pitch(10) sets your printer to 12 pitch, and @height(8) sets the line
xheight to 6 lines per inch.  The @sub(text) command creates a subscript out
xof 'text' and @super(text) superscripts the text.  If your printer is
xdefined as a DEVPLN (see scribe.h) these commands turn into null strings.
```

xIf, on the other hand, you have a DEVFNCY, the program will insert the
xcontrol codes that you have defined for your printer for the commands (and
xthe @u() @b() commands).
x
xCaveats:
x
xSince device.c has the actual ASCII printer codes in it, you may need
xto device.c to repair any mailer changes.
x
xUsing the @u() and @b() commands changes your line length in such a way that
xproff can no longer justify the line fully. That's why this program forces
xproff to default to .nj rather than .ju.
x
xCurrently the index command simply writes the indexed word to a file with
xthe name infilename.NDX and does nothing more. This is as far as the
xpreprocessor can go because it doesn't know about proff's final page
xnumbers.
x
xThe @enumerate() command does not always format the enumerated environment
xas desired; it indents the paragraph by one character.
x
xWhile the @need() command always gets through, proff disregards it at times.
x
xThe size of a single environment is limited to 32K simply because I was too
xlazy to figure out a dynamic allocation function for lines. It just uses a
xgiant static array, much larger than most should need. But forgetting to
xclose an environment can lead to overwriting a buffer if your file is large
xenough (probably about 30K or so). I've used it on 50K texts without
xproblem, but I'm rather religious about fences since GNU_EMACS understands
x@environment{} names.
x
xChapter, section, and string variable values are stored in static arrays
xinside a circularly linked list of variable structures. Values are limited
xto 255 characters, but no checking is done. Labels are limited to 31
xcharacters.
x
xThis is a one pass preprocessor. Environments can be nested, but string
xvariables cannot contain references to other variables. Example
x@string(name="Neil") @string(atarirep=name) "The Atari rep is
x@value(atarirep)" will not work as expected.
x
xThe @include(file) command does not really include the file; it just tells
xproff to do so. If the included file also contains directives for this
xprogram, it will need to be processed before proff includes it.
x
xThe argv parser creates an outfilename based on the infilename. Example if
xoutfile == FILE.MSS, the program will write out a file FILE.PRF to the same
xdrive and directory. If the @index() commands shows up, the file FILE.NDX
xwill be created. The program only uses four files because it frees up the
xstandard I/O files to use putchar(), getchar(), etc. for I/O.
x
xIt also looks into the STREAM structure, so if you have a braindamaged
xcompiler that doesn't let you find stdout->ptr you'll have to repair

```
xlastchar in envir.c.
x
xComing attractions:
x
x@case{atarirep,
x
xNeil, "Write this out to the file."
x
xJohn, "But don't write this."
x
xNULL, "[]".
x
xelse, "Got no name for atarirep."}
x
x@style(linewidth 39 pica) Style commands aren't too useful if you can't use
xpicas, micas, and ems.
x
x@time(GMT) (i.e. insert time using GMT standard.  This assumes you've set
xthe default time and the formatter time flag with the @style(time EST).)
x
x@note(Make this a fottnote, endnote, or inline note)  Endnote and inline are
xeasy, but footnote is real hard.
x
xI hope someone finds this program useful.
x
xRobert Royar

Fellow Netlanders,

I'm about to drop $1045 on a 1040ST with a color monitor.  Being a conscientious
consumer (tight wad), I've got a few questions.  I know the following topics
have been kicked around this group in previous months, so feel free to mail
your replies to me.
```

What's in the developers kit? Tons of (useful?) documentation, a C compiler, an assembler, a linker. Does it include a communication package to upload and download files from the UNIX system at work? How buggy/fast is the C compiler that comes with the developers kit? 300 frogskins is quite a bit, would I get my monies worth with this?

My other options for a C compiler are Lattice (slow, but I can get it for ~$125) or Megamax (fast but I don't know how buggy or how much it costs). I'll need an assembler that I can link with the C compiler. Is there any public domain C/assembler/linker?

I also need a communication package. From what I understand, a vt100 emulator has communication capabilities that will work on the UNIX systems at work. Does a public domain vt100 emulator exist? How do I get my paws on it if I can't upload/download?

What are good/bad documentation sources? Books? Magazines? I'm new to the PC world and I'm pretty much lost. If any experienced 1040ST person would be willing to mentor me via e-mail I'd appreciate it. Thanks.

Walt Kurszewski

I encountered another problem with spell.prg: I tried to use a dictionary
file with about 25,000 words in it, but I got a program error message. I
checked the file to see if it was in the same format that spell generates
when you add words to the dictionary, and it was. Is there some kind of
limitation on the number of words spell can check? Does it try to load the
entire dictionary into ram, for example?

     Would someone please tell me in what order the programs
in the AUTO folder run at bootup? I think I've tried every
combination possible (times, names), but I still can't figure it out -
the same program *always* boots first! Thanks in advance,

                                -ravi

Is anyone else besides me getting sick of getting many masgs of
tens of kilo chars in size of what looks like a drunk writing
teco macros?

My poor mail file blows up and chokes MM more frequently with such
stuff. why cant people just send a pointer to their program and let
those who want it get it or request it individualy. It used to be
considered anti-social to send such masssive files unsolicited.

People on usenet who have to pay phone charges will appreciate your
courtesy. My mailbox will love you too.

thank you for your support.

I agree with you about the heavy traffic. I've enjoyed getting all of
the great stuff about the Atari ST's but the GARBAGE is rediculous. I
never did count but I probably received over 150 - 200 messages weekly
just from this list. I don't have an ST but was(?) interested in
getting one. It seems to me that the actual expense of communicating
all of the encrypted code to my mail box alone is a price that I would
not want to pay and am sure that others feel the same way. So......

It's been nice but see you around. No more Atari mail for me; I've had
enough.

Mike

I have in my hand the new Sept/Oct issue of Atari Explorer that I picked
up from A local dealer at our local Atari club meeting last evening. He
said he had just received them Monday. It is 80 pages long, not counting
the covers. Quite a bit of information including a rather extensive
readers survey. This issue seemed to contain more news on the ST than the
8-bit but they emphasized Atari's commitment to continued support of the
8-bit computers. There is a review of the SH204 Hard Disk for the ST which
I had a chance to see runing last night.

According to rumors I have heard (I believe they come from CompuServe),
Toys 'R Us will be selling the 520ST with ss disk drive around
Christmas time for $250. This doesn't include monitor but since the
new 520ST's have an RF modulator, you can use a TV set until you rebuild
your savings account (:-)). It would certainly make an excellent starter
setup.

 For up/downloading with a UNIX you could use KERMIT, I don't know if
it is included with the kit or not. If not you could get from a local
user group. To ul/dl with kermit is fairly simple. At the UNIX end
you type kermit to get into kermit. To send files type send filename,
to recieve files type get files.   It's basicly the same on the ST
end.

I tested the SPELL program and was able to duplicate the error described:

When asked about the possible misspelling of a word, I deleted it by backspacing over it. The program quit, and the portion of the file right before the deleted word was erased.

I've looked at the source code, and have found the problem - the program thinks that it's done when an empty string is returned by one of the procedures. I'll fix it tonight and redistribute the source and uuencoded executable this evening.

Thanks for pointing out the problem!

>- Moshe Braner

Actually, it's even easier than it looks. Both GEM and OS-9 use
"vector tables" to access their "BIOS" routines. OS-9 could
simply be an additional group of vector tables. OS-9 also has
a nice capability in that it can use traps to access it's own,
or somone elses routines. The basic ingredients of VDI are
not that different, perhaps a few arguments would have to be
moved from one place to another.

As to 'IBM-compatible', anyone who has ever made a "plug compatible"
accessory for IBM knows how risky a proposition this can be. I've
worked for two different companies that stopped working for IBM
when the risks didn't pay off.

The main advantage of OS-9 is that object code compatibility can
be obtained without even so much as re-compilation.

Speed of execution might be a minor issue, but probably not significant
with processors running nearly 1 mips, and actual bit-bumping being
done by other chips.

According to the Magic Sac documentation, the Apple part numbers are either

324-00220-A (c) Apple 84 and 324-00221-A (c) Apple 84

or

324-00220-B (c) Apple 84 and 324-00221-B (c) Apple 84

The part numbers specify to Apple PROMS. I am using the Rev B parts, and they seem to work.

I have been told that Apple wants a high price for the parts, and that better deals can be made through distributers.

Hello...

Well, I have had my ST for about 6 months now, and I have developed a few problems or questions, which follow. Much thanks in advance for the help...

1) I have heard (or think I did) a rumor that the CP/M emulator was put into the public domain, and was available from the Atari BBS.

Any truth to this? As well, how compatable is compatable? Which video emulation is available?

2) I have also heard tell of a MS-DOS software based emulator which will be available shortly at around 100-150$. Any truth to this? I heard it flunks the Flight Simulator test, and is twice as slow as the IBM (which is awfully slow to start with). Can it run BASICA programs?

3) Finally, and most importantly, GEM under OSS Personal Pascal is completely useless to me, for everytime I run a program (one I have written, or the spelling checker recently posted), I get:

```
Bus Error Accessing $4675636B
Error in *unknown*
at PC $00FECC08
```

Is this a problem with Personal Pascal or my ST (gulp)? I have no trouble running TOS P.P. programs, or GEM programs written with anything else, so I'm lost... I have a 520ST with rev B. TOS in ROM and 512K. I bought the P.P. with the revised manual (all the mistakes had been fixed.)

I have tried in vain for a week or so to get through to OSS, but all I have managed to get is a busy signal and a sore finger.

FLAME ON:

I bought Personal Pascal for many reasons, but one was that I had heard that they offered "great" support. I don't know about that, but the support can be as great as you want, and if no one can get through because you don't have enough people to handle the masses, then we get screwed. I bought the system, I sent in my registration card, but I can't even get through on the 'Pay for it' line. Pretty aggravating... And I don't think providing a 'free' BBS is much of a solution, either. If I want that approach, I have to get a modem, and then pay for the privilege of long distance charges while I "sign up" and then keep calling back until I am answered. I can't ask questions without another phone call.

I have the same gripe about some of the retailers. Living in the wilds of the far north, the nearest STore is 300 miles away, and I am forced to use mail-order. For P.P. I shopped around, and decided that Black Patch offered the best deal. However, in a couple days of trying, all I got was the busy signal. Finally I said "to hell with them" and called someplace else that was higher, but that I got through to on the first try. They continue to get my business.

After all, if you are doing _that_ much business, it seems intelligent to add more staff and another phone line to increase your revenue. It doesn't seem, however, that this has occured to any of them at all. When I called 47th Street Photo to order my ST, I got through the first or second time, and was through with my transaction in minutes. I may be at university, but that doesn't mean my time isn't valuable.

FLAME OFF.

Sorry about the griping...

The Compaq machine may not be available yet, but the 80386 is. For now,
the 68030 is just something to be aware of when you design a 68020 system
so that you will be able to upgrade when the '30 becomes available.

Nope. Fry's Electronics (and supermarket) here in Sunnyvale had one in
already and sold it (I *think* the salesman said $5995). They said they
were expecting "several" more in "any day now".

They may not be widely available yet, but they aren't "vaporware" either!

Its nice to have, but required only if your OS demands it.

> Not until you have the 68030, or you make an entire subsystem
> plug in with a 68020 and an mmu, can you claim to have upgraded your Amiga

> the way plugging a 286 upgrades a pc.

I don't claim that the 68020 upgrade for a 68000 machine is like a '286 upgrade for an 8088 machine. I claim its a generation removed. The 8088 is an 8/16 bit processor, the '286 a 16/16. The 68000 is a 16/32, the '020 a 32/32. A processor with a good MMU can run UNIX, quickly, and have all the advantages of a protected OS. A non-protected OS can suffer from misbehaved programs and slow context swaps (if its multitasking, which the MS-DOS operating system emphatically isn't. Oranges vs. oranges, remember). A Turbo upgrade for an Amiga can deliver much the same level of performance as a Sun and still use standard off-the-shelf Amiga software and operating system, and it can take advantage of the extra capabilities of the 68020. MS-DOS runs fine on a '286 PC, but it can't use the extended memory addressing capabilities -- unless you kludge it, MS-DOS has a ceiling of 640K. AmigaDOS has a ceiling of 4 Gigabytes.

I wouldn't try to run UNIX on a basic Turbo Amiga; UNIX isn't designed to run well without an MMU; the context swapping between processes is going to make it a dog. But the Amiga Exec was designed to provide a fast multitasking environment on a machine without an MMU. It supports 68000, 68010, and 68020 processors in a processor-independent way; the Amiga Exec knows which processor is in place and provides functions to handle the differences, like the different exception stacks. All the AmigaDOS software will work as is with the 68020, or it can be upgraded to take advantage of special 68020 enhancements. These upgrades, however, can be incremental, as each of the many software subsystems in the Amiga Kernal and DOS can be replace independently of each other. How much of the '286 instruction set, etc. will even work under MS-DOS, assuming I were to, say, rewrite the floating point libraries for the '286 and '287 coprocessor?

Of course an unprotected multitasking environment is dangerous for poorly behaved programs, but so is a single tasking environment on a machine without adequate hardware support (like a PC). I wouldn't expect to see a good UNIX running on the Amiga without an MMU; then again, an 80286 UNIX has to deal with its own set of inefficiencies, namely the 64K paging limitations that still exist even in protected mode. For a state of the art UNIX environment I need to an an MMU to my Amiga, you need to add a '386 to your PC. An integral/standard MMU is a good idea; Intel finally go one right :-).

> In the first place, msdos, while not taking advantage of the functionality
> of the 286 or the 386, is certainly not a kludge when run on them.

True. Lots of folks think the 8086 modes are kludges; I believe they're not. And the problems with the '286 native mode and MS-DOS are due to both the design of the '286 and the design of MS-DOS.

> In addition, when you go from one type of 68* based box to another, you
> also need to rewrite the operating system, because the memory management
> systems are incompatible.

Not helped much by the two different late-coming 680xx MMUs. I know, any

standard MMU is better than none at all.

> People have also generated 286-based cards that plug into plain old IBM pcs
> and have gained a significant performance upgrade, while running their old
> software. I'm sure the same thing can and will happen with the 386.

That's really only the advantage of going to a 16 bit (or 32 bit) bus
versus the old 8 bot of the 8088, plus the faster speed of the thing. But
like I said, I can get a much more significant increase in power with the
68020 card in the Turbo Amiga -- double the clock speed, double the data
fetch, and extend that memory limit to the full 32 bit address bus. Now
I know that this can't be done with every 68000 based micro; many of them
do thing that require a 68000 only. That's an OS design issue. And why
I'm glad I have an Amiga.

> And Unix implementations for 8086-based chips have been floating around for
> at least 5 years. MS-DOS already is a 16-bit os, and always has been.
> When going from a 68020 to a 68030, you will have to rewrite the os to take

> just have a little faster 68020, much like you can use a 286 as a faster
> 8086. How about if we compare apples to apples? Can you say "incoherency?"

I'll leave the "incoherency" to you. You're flaming for running a 68000
with no MMU, then you suggest Unix for 8086-based chips? If I want
segmentation as a form of memory mamagement, there's nothing stopping
me from requiring my 68000 environment to support only register
relative addressing. But anything that _requires_ 64K segments shouldn't
be bothering with UNIX. And as I said, my move to an '020 or '030 already
gives me much more than just a faster 68000. To use an MMU would require
a few sections of the OS to be rewritten, but its no big deal. The
hard part is going the other way, which is why memory management is
required for UNIX speed, protection issues aside.

>>>>>>>>>>> Eat away you monster!!! <<<<<<<<<<

I am an avid C++ fan who is about to get an Atari 1040ST and a C
package. My question is: is there any way to get a C++ package for
the 1040? Alternately, is there any C source code for CC that I can
get my hands on?

Thanks in advance.

Why do you need multitasking to filter a region through a command?
As long as the system provides a way to specify what program to use
as a shell you should be able to do filters.

The windowing system on the 6300 Plus is not really a general windowing system (at least on the ones I have seen. The ones I have seen are kind of old, so this may have changed).

When you run the thing, you get a box on the screen that looks something like this:

```
XXX Office XXXXXXXXXXXXXXXXXXXXX
X                               X
X -Administration               X
X  Commands                     X
X  Printer Information          X
X  Unix System                  X
X                               X
XXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXX
```

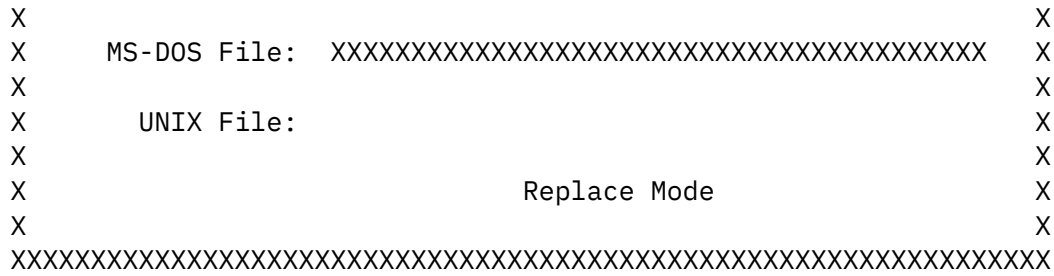
The "X"s are really solid rectangles of inverse video, and the command with the "-" next to it is in inverse video. You use the arrow keys to move up and down the menu and hit return to select an item.

Some commands bring up other menus, for example, "Commands" makes the screen look like this.

```
.Office.................
.                       .
.  Administation        .
. -Commands X Commands XXXXXXXXXX
.  Printer  X                  X
.  Unix SystX -Color            X
.           X  DOS-to-UNIX      X
.............X  Logout          X
          X  Shutdown         X
          X  UNIX-to-DOS      X
          X                   X
          XXXXXXXXXXXXXXXXXXXX
```

At the bottom of the screen are labels for the function keys. It also supports something that is like what a Mac user would call a Dialog Box. For example, selecting "DOS-to-UNIX" clears the screen and draws this:

```
XX DOS-to-UNIX Copy XXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXX
```



Compared to Mac, ST, Amiga, etc, this is not that impressive. Compared to MS-DOS, it is perhaps something to get excited about.

The way the 6300 Plus runs DOS tasks is kind of interesting. UNIX runs in protected mode, and DOS wants to be in real mode. They have implemented some external (to the CPU) mapping hardware so that they can have memory that is not available to real mode. They put DOS in the memory that is available to real mode, and all the UNIX stuff in the memory that isn't.

To switch to the DOS task, they RESET the CPU (this is the only way to go from protected mode to real mode). The DOS task then runs in real mode. When it needs to do something that UNIX needs to know about, the external hardware makes the CPU go back to real mode and UNIX runs. (There is also a watchdog timer to force this if a DOS task gets into a loop).

The person who thought of this is either a genius, or insane (probably both!)

Check the default shell field of the login entry of \etc\passwd for the
offending login. Make certain that the csh.prg file can be found. You should
also check the user's login.sh file to see if the path is being set to
something weird.

Summary: vt100 emulator

I have ST-TERM from Commnet Systems v2.0. It has a fairly complete
vt100 mode. I have been able to use it with eve on vms, and with
vi on unix without any problems. It does lack 132 column mode, and
half and double size characters... and some other esoteric features
such as a reverse video that works consistently.

all in all I would probably buy it again...

Obviously, a non-amiga-owner. Anyone who has had experience whith
the "Down's Syndrome" PC emulator (Transformer) realizes that software
emulations (interpretive ones) are absolute SH*T. Don't get me wrong,
I think the 386 is gonna lose in the CPU wars.

COME ON GUYS!! KEEP THIS DISCUSSION IN net.micro.68k or net.micro.pc

OK??

Actually, one can easily support this claim. In both cases, you still have
the same level of memory protection as before. Correct me if I'm wrong (and
I know you will :-)), but MSDOS doesn't work in the 80286 protected mode, does
it? Since this is this case, upgrading to a 286 does not give any more
protection when using the standard OS. Sure, you have memory protection for
UNIX and its clones, but if that's what you're talking about, then you're
comparing apples and oranges (which is quickly becoming a very popular term
in this discussion).

I enjoy just watching the competition! The one-upmanship of Motorola
and Intel makes for a furious rate of advance in technology. Let's
just have a clean, fair fight and we all benefit.

> And what about the new family jewels? Should I feel vindicated that Mot
> has finally decided that on-chip memory management is a good idea? ...

Only when Intel decides that on-chip caches are a good idea. The 68030
has *both*. So does the Clipper, by the way. The MIPS chip set likewise

does the MMU and half (the hard half) of the cache. Where's Intel?

> ...what about performance? Why would a new, ultra-high end user choose

> the promise of delivering more sooner) and are available, in some semblance,
> today?

Probably no particularly good reason except compatibility. I notice,
however, that the line of argument has shifted slightly: we don't hear
the word "Intel" any more.

Really? 386-based machines have just barely started shipping. And all
the software runs them as if they were 8088s, or 286s at best if you're
lucky. 68020 machines have been in the field, with software support, for
quite some time now. I'd say the 020 has a half-generation lead.

[==> Followups have been redirected to net.micro.68k <== If you care
about this topic, please start reading about it there. The mac/amiga/atari
users have enough to talk about without Intel/Motorola flames. I'm just glad
nobody has tried including net.micro.pc, then the flames would really start!]

I believe it is correct to compare the 80386 with the 68020, on a feature
by feature basis. They are both the first 32-bit processor from each
company, have similar cycle and instruction times, addressing capabilities,
etc.

In the past Intel has been first to market each level of chip.
However, they spent too much time at the 16-bit level (on the 186 and
286, both of which took longer than expected), and Motorola worked hard
to get out of the gate first at the 32-bit level. (My favorite "why
IBM chose the 8088" rumor is that Motorola couldn't build them 1/4
million chips the first year and Intel could since they had been
ramping up longer. Be interesting to see if Motorola's taking the lead
at 32 bits makes any difference now.)

My impression is that the relative power of each chip relates strongly
to its design date. Thus, Motorola chips have tended to be more
powerful than the corresponding Intel chips, because they were designed
slightly later. The 80386 should be faster than the 68020, since it is

coming out about a year later. They made a big mistake in leaving out
the cache, though they did put in a neat feature for interleaved memory
access, so it probably runs in roughly the same speed range unless you
give it a fancy memory subsystem. (If a fancy memory is assumed,
though, then the faster possible clock rate on the 68020 comes into
play, maybe making it an even heat again.) The 68030 will be faster
than both, since it will be yet another year later. And so on...

I'm not going to argue the merits of Intel versus Motorola. It is clear
to me that both have learned from each other. Now it is up to us, the
users, to learn to write our stuff portably so we can move it to the machine
of whoever is learning the fastest at each point in time.

Okay, we'll compare apples to apples: how's the 32-bit-mode code generator
for the 386 coming? If you don't have that, you just have a little faster
80286. Rewriting the code generator and recompiling everything strikes me
as rather more work than hacking up the MMU section of the kernel.

Especially since the 286->386 conversion is also going to mean hacking
up the MMU stuff to cope with 32-bit addresses.

>November 1985). So question one is, "has anyone other than those at
>CASE gotten this program to work?"
>
 I know of alteast 2 dozen people who have gotten make to work outside of CASE, and with various compilers (lattice, megamax). I ran it through Mark Williams too, and it works just fine.
 Most people who have been having problems with 'no memory ...' type of errors, have been making the mistake of linking make with the version of gemstart.o that was distributed with the development system. That particular version only reserves 1K for stack+heap, and gives the rest back to the system.
All that is needed is that you edit gemstart.s and on the line that reads
     add.l   #$500,d0 * d0=basepage+textlen+datalen+bsslen
*   (plus 1K of user stack)
and change the $500 to some much larger number like $4000 (16k). Better yet, use the new gemstart.s available on CompuServe, that has the various memory models. I hope that this is your problem.

As far is touch goes, both the stand alone touch program, and the touch function within make, get the current time from the IKBD and not from Gem's counters. So if you only set the current time via the control panel, and have not set the IKBD's time (they are independent counters, and the

control panel acc. does not set the IKBD time) the time you will get
will be wrong. I am almost certain, from your description of the problem,
that this is the case. The reason i chose to read the time from IKBD rather
than from Gemdos is that the IKBD clock survives resets, while the Gemdos
clock does not. Besides, i have long ago, thrown away the control panel
accessory.
To set the IKBD clock there are atleat a dozen PD programs. Many of them
sit in the auto-folder. Almost all of them set both the counters.

-My second question has to do with the last cast in the structure
-initializer. Here's the scenario. My dev pack has been ordered and
-should arrive next week, so I compiled the code with the CP/M-68K
-compiler (which is identical to the early ST version right down to the
-serial numbers). I had a friend compile it on the ST with his DEV
-pack and he got the same errors. The early Alcyon compiler only
-supports unsigned ints, so uchar is defined as char in a header file.
-But the code parser (c068) balks at the coercion with the error
-"invalid initializer" which means I tried to init a variable with
-something other than a constant. Even the cast (char)'\0' got the
-same error. Now I know the last element of that structure has to be a
-character constant or the structure will not be filled properly.
-
-The code generated for a structure like this goes ahead and fills the
-remainder of the space to allign on a word boundary, but the size of
-the last element determines how that element will actually be stored
-and accessed. Structure initialization and size has been a known bug
-in the Alcyon compiler at least since 1983. One problem with this
-structure is that all of the beginning elements are 32 bits long.
-Alcyon has trouble, and always had, with structures or function
-parameter lists that all have the same (long) size.

     All of the above comments are appreciated. I think you will
find that the new version of Alcyon V2.14 handles structures quite well.
Maybe i should have checked with my old compiler disks, but i did'nt since
the new version had been out for more than a couple of months when this
article was posted.
I guess (have'nt tried) you can go ahead and declare uchar as an int, and just
put a '0' for the last initializer, and it should tide you over till you get
your devl system. Sounds like your friend needs to get the dev. sys. upgrade
too.

-Another minor beef. If you
-
-#define uchar char
-
-Sometines the preprocessor has trouble in an expansion that involves a
-cast. If you
-
-#define void
-
-casts again can lead to difficult to track errors. Is there a reason
-to avoid typedef in these situations? Why not use

```
-
-typedef uchar char;
-typedef void int;  /* after all Alcyon expects int returns by default */
-                   /* even when none are specified.  Check the stack */
-                   /* popping code it produces after a jsr */
-
```

voids are NOT int's. V2.14 supports voids just fine.
I just tried a small example. It does not produce any extraneous code. Besides the stack popping code is there to pop the arguements off the stack. A value, if any, is returned in d0, so the stack popping code has nothing to do with the type of value returned by a function. I think 'typedef void int' is a bad idea, as any compiler (such as v2.14) will complain because void is now a reserved word, and can't be used as an identifier.
I do throughly agree on your point about using casts. Typedefs should be used when possible (see comment below too).

>Defines are hard to track down in a preprocessor output file because
>they all dissapear. But a typedef follows through that output, and
>you can see what a cast or value is. DRI used to
>
>#define FILE struct _iobuf
>
>That made a file definition bug a real bear to find. However,
>
>typedef FILE struct _iobuf;
>
>is more logical and closer to the intentention of using FILE
>structures in the first place.
>

Totally agree on the above point. Since i ported neil's code i just followed the same style. I usually do use typedefs.

>While I'm on the DRI soapbox. I compared the AR68 output for gemlib
>to that for the old clib libraries (is AR68 available for the ST
>yet?).

Yes, a working version comes with the dev. sys. update. there is also a Pd version available.

> .....
>effort to move to the ST. It's ridiculous that there's no equivalent
>to "real" xmodem i.e 1024 packets, true CRC, batch files, 19200 baud,
>scripts, etc. in the ST PD library. 19200 is great for moving files
>between the ST and your other computer, whatever that may be.
>

I routinely use xmdm to transfers files and in terminal mode at 19.2K. One of the person's here has also implemented chuck fosberg's (sp ?) Ymodem protocol (rz/sz) and that handles 1K packets pretty well. Hopefully it will have adapting windows one day. I agree that we could use PD gems from the Cp/m world too. So as the old saying goes "Put your money where your mouth is" and post some!

Is there a draw/paint program available for the ST that works with a
monochrome monitor? Any pointers and reviews will be highly appreciated.

(Minor flame on)

It is annoying that "standard" software included in the package that you buy
(in this case, NeoChrome) does not even work. Why include it at all instead
of a reasonable substitute that DOES work? It's like buying an expensive
tape deck with auto-reverse, and then finding out that it doesn't work with
the particular tape head they used in the deck.

(Minor flame off)

While I'm on the subject, does anyone know why the monitors were designed to
be incompatible? Especially since the monochrome is higher resolution than
the color, it would seem natural (and pretty trivial) to design them such
that you would get a grey approximation to the color display if you had a
monochrome plugged in. I'm sure compatibility wouldn't hurt the sales any.

One further query: Does anyone know of a "calculator" desk accessory?

Thanx... -- Ashwin.

Quick trivia question: How about MS-Windows? That does multitasking...how
   well does it work an 80386? I've almost been tempted to go to Computer-
   land and give it a try...

Summary: Dealer practices.

Much of this has to do with the dealer. One dealer here
took prepaid orders of many times their agreed on allocation
schedule.

Other dealers have been taking no back-orders and are still selling
them as they come in.

The dealer that took the back-orders was trying to corner the local
market (which would be easy to do here). Atari has had the wisdom
to protect the supply to other dealers. Without that protection,
the ST's would ONLY be available mail-order. Not the best choice.

Keywords: frmtplus, veroff, veron
Summary: Shar file containing 3 uuencoded programs

Tired of slow floppy i/o? Extract the following and read the readme file.

```
#! /bin/sh
# To extract, remove mail header lines and type "sh filename"
echo x - readme
sed -e 's/^X//' > readme << '!FaR!OuT!'
XThis shell archive contains the following files:
X
X    veron.s       source code for veron.prg
X    veron.uue uuencoded veron.prg
X    veroff.s  source code for veroff.prg
X    veroff.uue    uuencoded veroff.prg
X    frmtplus.uue  uuencoded frmtplus.prg (from Atari BBS)
X
XFrmtplus.prg is an executable version of the basic program published in
Xthe September edition of ANALOG magazine.  Place it in the AUTO folder of
Xof your RAM TOS boot disk and then format disks as usual from the desktop.
XThese F+ formatted disks contain extra disk format information at the end
Xof each track, in the area where the "unused" sector would be located.
XRead/write operations on these disks are much faster than read/write
Xoperations on vanilla TOS formatted disks.  So much faster, in fact,
Xthat it makes the extra effort required to format disks this way _well_
Xworth the effort.  Please refer to the original article in ANALOG for
Xmore info.
```

```
X
XTo compliment FRMTPLUS, I've written VEROFF.PRG and VERON.PRG.  Veroff
Xturns off the floppy verifies, thereby increasing disk write throughput
Xby a factor of 2.  I've installed veroff in the AUTO folder of my ROM TOS
Xsystem disk and have experienced no problems with it to date.  On those
Xrare occasions when I'm feeling particularly paranoid, I execute veron
Xto turn the verify back on again.
X
XFor those of you without uudecode, simply assemble the .s files, and then
Xlink and relmod with no other libs - as in:
X
X    as68 -l -u veroff.s
X    link68 [u]veroff.68k=veroff.o
X    relmod veroff
X
XEnjoy.

>
>Oh, this is great. Yet another paper product. This one, they haven't
>even had a press release on! I guess it must be more than a year
>away (:-)).

Ken has a right to be skeptical on this one! It also illustrates the silly
ways in which 3rd and 4th-hand information propagate around. I quote what
the Byte issue says: "Sources with Motorola's microprocessor group (Austin, TX)
confirm that two new central processing units will be released by that
company in the near future. (Stuff on 68030)...Due in the first quarter of
next year is the 20-MIPS 78000 CPU. Sources said the 78000 is a RISC processor
that represents an evolutionary progression of the 68020."

What we have is: a) Somebody from Moto talking off-the-record to somebody on the Byte staff. It is possible that not all Moto people would agree. b) Byte prints this, so now it looks official-looking. c) Somebody else mentions it in the net, and now, a chip that (I'd guess) hasn't yet been taped out "totally blows away the RT PC." Now it sounds like it exists right now... No wonder people get confused between claims and reality!

One has to wonder what even the 2 sentences in the article actually MEAN? "Due in the first quarter.." Does that mean:

a) Appears in a machine you can login on?
b) Appears in a board?
c) Production quantities?
d) Sample quantities?
e) First silicon?
f) Announcement of when any of a-e will happen?

"20-MIPS 78000 CPU" Does that mean?

a) Runs at 20Mhz, and can do peak 1 instruction per cycle?
b) Is 20X a VAX 11/780 doing real work?

Note that the conversion from peak MIPS to VAX-equivalent MIPS (or any other kind of real-live MIPS) can take on radically different factors: for example, on 68020s, the division factor seems like 4 (i.e., 16.67Mhz designs gives 8 peak Mips (2 cycles/instr) ==> 2 VAX mips. Clippers have a factor of about 6.6 (33 peak Mips ==> 5 Mips (according to published claims)). Depending on what the 78000 really will be, it might be as low as a 5Mips part (one would expect it to be higher).

"RISC processor that represents an evolutionary progression of the 68020." What does this mean?

a) Does it run 68020 object code?
b) Does it run a subset of the 68020 instructions?
c) Is it different object code, but "philosophically like the 68020"?

Sigh. As one can see, if one reads the literature uncritically, things that sound like information can be found to be rather content-free, i.e., "real" information is found to be "virtual."

Note: none of this is meant as an attack on the 78000, but on the weird process by which information leaks around and is jumbled up. As far as I know, the 78000 hasn't been announced by anyone for the record, and is mostly discussed with Moto customers (existing or potential) who want to do high-end systems and show signs of picking other vendors' micro-processors. Perhaps someone from Motorola might care to comment on the original article: one can choose to believe a vendor or not, but nobody should ascribe high credibility to 3rd-hand off-the-record comments, or knock the vendor for such "information".

Your assertion about classifying 68k based machines is more or less correct;
I wouldn't want to lump the Amiga and the Sun together. Yet. But sooner or

later Commodore will get their act together, and you can bet on the existence of an MMU in Atari's TT box next year, and that whatever design one uses, it will be infinitely easier to live with than the Intel segmentation design. A simple matter of extracting limited function from a limited design.

>> Another important point to make is that operating systems implemented on

>are incompatible.

You just walked down the wrong alley for an Intel person. I dare say that there are far more diversified and completely alien implementations of the MS-DOS BIOS and kernal than there ever have been 68k implementations of Unix. In fact, the amount of dirty work needed to port Unix memory management from one 68k system to another pretty much is based on only two variables: which version of Unix, and whether or not you're demand paged. The minimum functionality required to run Unix well is easily accomodated by just about every 68k MMU design I've ever seen. What's a '386 user to do, use the warped `MMU' inherent in its predecessors? No...you need a rewrite. Motorola passed that trial years ago when the '010 was introduced.

> People have also generated 286-based cards that plug
>into plain old IBM pcs and have gained a significant performance upgrade, while
>running their old software. I'm sure the same thing can and will happen
>with the 386.

What a coincidence! Just about everybody else in the world has too! And if you're not convinced, I have some Apple-II+ accelerator boards I'd like you to meet.

> And Unix implementations for 8086-based chips have been
>floating around for at least 5 years.

Amazing. Commercial Unix implementations for 68000-based machines have been floating around for well over 5 years; check the ads in your old Byte issues.

>MS-DOS already is a 16-bit os, and always has been.

What are you trying to say? "And it always will be?" We're not discussing 6502's here. The 68k family is already a 32-bit processor, and always has been. Bus sizing is just another one of its strengths, if you will.

> When going from a 68020 to a 68030, you will have to
>rewrite the os to take advantage of the memory management that the 68030
>provides...otherwise you just have a little faster 68020, much like you
>can use a 286 as a faster 8086. How about if we compare apples to apples?
>Can you say "incoherency?"

Can you say "Yes, you are becoming incoherent"? When going from a 68020 to a 68030, you will have to throw away that PMMU chip you had sitting next to it. Code changes? Motorola claims you won't need any. I'll be more than happy to throw away another large power-sucking chip; I need the real-estate anyhow. When going from a '286 to a '386, you will have to rewrite the OS to take advantage of a real MMU. You guys DO have a real MMU, don't you? Otherwise, you have a little faster '286. As for improvements in Motorola's performance, a large number of programs benefitted wonderfully from the DBxx change in the '010, and that's the name of the game. Otherwise, why would NEC try to market the V20/V30 family?

>--
>The above views are personal.

>I've seen the future, I can't afford it...
>
>Ken Shoemaker, Microprocessor Design, Intel Corp., Santa Clara, California

Yes, the good people of Oakhill are jumping the gun a bit, but it isn't going to bother me a bit. As far a Joe Blow is concerned, his computer suddenly became faster and less power grubbing with a minimum of hardware redesign on my behalf. As far as I'm concerned, I just won an MMU and a data cache and saved myself a lot of money. Keep your iAPX toys, guys; I might look you over if you start running circles around Vax 8800's. If.

The opinions expressed within are entirely mine, and may not reflect the views of the University of Maryland. But a hell of a lot of my friends share them.

     Hi, I just would like to bring up a new topic to think about.
I find that working at the chip level can be a great joy but *most* consumers
do not. They mostly run programs and only care if they run -fast enough-.
As far as writing programs go the compiler is where the real sweet occurs
yet compiler writers are *few* compared to end users. Then we have
to weigh just how many *good* applications can be addressed with only
a compiler rather then an assembler. This problem is more complex
-to be sure- but I would say that the compiler that is most mature
is the winner (at the time). That is because a buggy compiler can
cause much pain to developers... Market competition has to occur
to 'debug' the compilers etc.... What I am getting at is by no means the
fault of hardware design -just the first in high volume to market wins-...
I have a 68K and an 8086! but I can use both... Ok everybody -

lets here it for 'to each his own' (any cheers?). I think most people
don't get down to the hardware level like the rest of us. Well for now I'll
think about getting so sleep and dream of some *real* cpu's not like
the toys we have today but say in 10 years. (You know 10 years from
now when we have the computing power of a CRAY in a kid's toy.....:-)

Mike Gore
Institute for Computer Research.

[The following is a uuencoded program that will kill the line eater:]

> > > O F F I C I A L A N N O U N C E M E N T < < <

At the risk of contributing further to the problem, I hereby make
the following announcement:

This line of discussion has ceased to be interesting. As a result,
the signal-to-noise ratio has gone way down.

Talking about vaoprware, after I think about it a while, only depresses me. I'm interested in what I can do now, not next year. Waiting is not my thing, doing neat stuff is.

We already went through The Boing Wars once already. Face it: designers will create wonderful ideas and stupid mistakes. Some have more of one than the other (I will privately mail my opinions to anyone who's interested; I don't think there will be a big response, do you?). This is the point: If machine 'x' really is sh*t, then why did person 'y' buy it? Furthermore, why did person 'y' keep machine 'x' after "seeing for himself" that it was sh*t? One machine will not please everyone, and that's why there are all different kinds. This is one of the advantages of living in America.

Please redirect followups to these threads of thought to the appropriate news group; I'm getting tired of sorting through 50 articles a day, only half of which are remotely interesting. To get an idea of what it's like, visit net.jokes sometime ("There are 320 new messages in net.jokes, only 7 of which are funny. Read now [ynq]?").

Don't followup to this article, as talk.bizarre might get annoyed (snicker, snicker...).

I found the comments about people having problems getting 1040's at all interesting, especially because when I went to buy mine, I plonked down the check and walked out with a system. This makes me think that the problem might be with individual dealers doing strange things..

The next file that I'll post is the OSS Personal Pascal source code for an amusing graphics demo program that I've written.

I would post the binary, but I do not have uuencode for my ST. If someone would send this to me, I'd be very grateful.

Enjoy the program,

Eric Bergman-Terrell (CSNET Address terrell@ohio-state)

I forgot to mention that it will work only on monochrome systems. However,
it should be easy to modify it to run on color systems.

Balma and Fitler's book contains references to three Gem Functions that
are available on the IBM version of Gem. These functions are not listed
in the Abacus book. They are:

appl_find
appl_tplay
appl_trecord

Are they missing from the Atari implementation?

At last.....Tomorrow I will post UniTerm V1.4 to the net, look for following
files:

      UniTerm 1, Part 1 of 6
      (Read.Me,UniRsc.UUE)

      UniTerm 2, Part 2 of 6
      (Keyedit.UUE)

      UniTerm 3, Part 3 of 6
      (Uniterm.a)

      UniTerm 4, Part 4 of 6

(UniTerm.b)

UniTerm 5, Part 5 of 6
(UniTerm.c)

UniTerm 6, Part 6 of 6
(UniTerm.d)

A update of the documentation is still being done and will be sent to the sites which didn't receive the original posting.

Wouldn't you know, I managed to mess up my only posting in months. The veroff.uue is actually _another_ copy of veron.uue. Hoever, the fix is simple enough: you can 1) actually assemble the veroff.s file, or 2) edit the uudecoded version of the bad veroff.uue. To do the latter, you must replace the 0xffff at offset 0x2e and 0x2f with 0x0000.

```
0000000  601a 0000 0026 0000 0000 0000 0044 0000
0000020  0000 0000 0000 0000 0000 0000 4ff9 0000
```

```
0000040  0066 42a7 3f3c 0020 4e41 5c8f 33fc ffff <--- replace ffff with 0000
0000060  0000 0444 2f00 3f3c 0020 4e41 5c8f 42a7
0000100  4e41 0000 0002 0000
```

Sorry for the foul up.

-Rich

lineater ? we don't need no stinkin' lineater !

the next 4 postings (which knowing the net will end up preceeding
this posting (:-) contain a brief explanation of the features of
the latest port of microemacs 3.7i and the uuencoded version. to get
it; remove heading etc. from the 4 postings, cat them together,
unshar them, and uudecode emacs.uue. the sum's for the files follow:

```
56189    99 emacs.shar
43567    68 emacs.ttp
40157    94 emacs.uue
54370    30 part 1 of 4 (without headings, .signatures etc.)
45955    32 part 2 of 4
29676    32 part 3 of 4
01530     7 part 4 of 4
```

and just for the heck of it

```

The telex number for Atari US is 172508 ATARICHQ SUVL

Contact Cindy Clavernan.  The price is still $300 but she will have to tell
you what shipping costs to add.

I doubt there's any difference between the US kit and the one in France, but
it's your nickle.
```

Ubiquitously,

Yes, it is a complete rewrite of everything in the developers documentation.

> If the retail documentation does NOT cover all of this stuff, I'm going

What $50? There is no separate $50 fee, just the $300 for the kit.

The 1040ST's are in production and on their way. We sold out due to a
spectacular Summer.

Accepting money for a product which cannot be shipped does not build up

assets -- there is a liability added to the books for each undelivered
machine.

And the shortage is a situation which will be cleared up momentarily.

We hope to make it available shortly. One snag -- if you download CP/M and
the utilities, there is no way to get the utilities into the CP/M format.
The utility to transfer files from TOS disk format to CP/M disk format
happens to be written under CP/M. If any of our European friends know of a
solution to this (it is rumored that CP/M is being passed around on BBSs

over there) please let me know right away!

The PC emulator will be a bit more costly than described and will function a whole lot better. It will be approximately the same speed as a PC. It should pass the FS test.

Hello, I was wondering if there is any music studio song players
available similar to the Sid player for the C64. I just want to
download ".sng" files from the local BBS and play them with out
needing the music studio package.

> Well after a bit of digging and disassembly my brother (a sharp troop) found the correct combination to get the reset surviving RAM disk to play as drive F: in a HD system (Atari 20meg). I don't have the code right now handy but will post it this weekend (the hex file again or uuencoded). In essence the patch was applied to two places. First, as was mentioned before on this news group you need to change the bit set in the 'drivebits' variable down in low memory. The BSET #3,d0 needs to be BSET #5,d0 (for drive F:). The other patch is applied to the compare instruction in the code that is executed when RWABS calls the RAM Disk. The RAM disk checks the device number and if it's not the right number it passes control through a JMP instruction to the Hard disk vector the RAM disk saved at boot time. As I said I can't remember off the top of my head what the exect CMP instruction is and what it must be changed to, but you should be able to find it. If not, just wait for the posting. The above patches imply that the RAM disk need be executed after the hard disk driver is installed, so it may take over and save the hard disk vectors.

There are actually two more places that the drive number is used: in the code that is executed when GETBPB (get bios parameter block) is called and the code that is executed when MEDIACH (media change) is called.

Also, I believe that the hard disk driver thinks it owns drives C:, D:, E:, and F:, although perhaps it gives up control of F: if you are not using that partition. The safe thing is to install the ramdisk as something > F:.

> Anyways they are both living happily in the system. 1 360k drive A:, 1 720k drive B:, 1 4meg drive C:, 1 6meg drive D:, 1 10meg drive E:, and 1 500k drive F:. Veerrrry Niiice!

Have you done a SHOW INFO on drives D and F? If indeed you forgot to correct the device number comparison for the GETBPB call, then I would expect both to be incorrect: GETBPB calls for drive D would be intercepted by the ramdisk driver and show a size of only 500k, whereas calls for drive F would be passed on to the hard disk driver, which would do who-knows-what. Perhaps your brother actually fixed all three calls.

Summary: C compiler info

A couple of miscellaneous notes about ST C compilers...

Mark Williams and David Beckemeyer are supposedly working together to make their use of environment variables (and on how they store environment variables in memory) compatible so that programs can be called from either shell regardless of what compiler/runtime package was used.

One reason for the difference in ST object file formats is that the "standard" GEMDOS format has a pretty limited symbol table (only eight character names & the Alcyon compiler prepends a character to externals so that you are limited to seven characters). The GST linker provides 32 significant characters; Mark Williams provides 16 significant characters; Megamax provides 10.

> released their SCSI interface and clock board in mid August. Does anyone
> know if they have done so? oe btter yet, has anyone actually got one and
> have anything to say about it?
>
Beckemeyer (actually Berkeley Microsystems) released their SCSI/clock board during the recent Atari expos at San Jose and back east. Some details:

    It costs $135 for the card or $250 with an adaptec controller.
    (mounting brackets available for $8)

    They have an integrated 34.4 Mbyte drive (all up) for $1200.

The card does not support full SCSI. It will only address one device on the bus and not deselect for the full "daisy-chaining" effects of SCSI.

Their address...Berkeley Microsystems
        1107 El Centro Avenue

Oakland, CA 94602

(415) 530-3436

I have no affiliation etc......

To Peter Jaspers-Fayer

Make sure all cables and wiring are connected securely, sometimes they vibrate loose.
If that doesn't work, unplug the circuit cards and replug them in. Sometimes all the contacts are not making contact and the boards need to be reseated.
Make sure you ground yourself before (and occasionally while) you are handling the boards to avoid damaging the boards with static electricity. This is probably rare but if it still doesn't work, at least you know you haven't added anything to the problem. You can ground yourself by touching a cold water pipe or the screw that holds the cover on a conventional wall socket plate or switchplate..
Come to think of it, check to see that any socketted chips are seated properly. Sometimes all the chip pins are not making good contact. Also look for solder bridges or conductive dirt shorting circuit traces or chip pins.

Sounds very interesting, but how does it allow you to run multiple
processes from the ST's on console/screen? Via UNIX & suffix to
command lines?

Also, on the Amiga, a Command-Line-Interface can be run from the serial
port (i.e., a terminal) with a new aux: device that just became available,
but it suffers from the problem that any program that doesn't use STRAIGHT
stdin/stdout isn't going to work too well. This includes using
Requesters(Amiga)/Alerts(?)(Atari) or even windowing.

I guess this MT-CSHELL would have the same problem, huh? I was AMAZED
when I hooked up a terminal to the ATT7300 (UNIX box with blitter/windowing
on the console) to discover that the windowing worked on the plain ol'
vt100, too! Now that's thoroughness. T'would be nice if these cheaper
boxes could do that, too. Must take gobs of code to do both, though.

     Paul.

I have both the 20 meg hard disk and the MW compiler. I'm quite pleased with
both. As far as ram disks go I had the same problems with trying to
install it as C D E or F. These seem to be reserved for the hard disk in
some way (Magic?). If you install it "anywhere" after F there are no problems
(provided your ram disk software lets you do that), I have mine installed
as "M".

The Mark W. stuff seems to be as close to a UNIX C environment as you can get
without UNIX. It has a complete UNIX "MAKE" and comes with a version of
uEMACS that is quite usable. If you put most of the stuff in a ram disk
most compiles are faster than on a VAX. It also comes with all the GEM
stuff you need. What they really need is a good debugger like "dbx".
I'd buy it again.

Whoa!!!!! The 68020 (and presumably the 68030) transfers long words (32 bits,
4 bytes) on its 32-bit data bus. What you are tripped up by is specmanship!
40 Mbytes/sec is 10 Mlong-words/sec. This comes to 100 nsec, which is fast,
but doable.

                        Steve Rice

the new version of MicroEmacs 3.7i (posting as soon as i get a few final
bugs out) will support both (40x80) and (25x80) on b/w monitors, why not
50 ? i dunno...

Wait a minute. They couldn't make it look like the Mac, so they make it look *worse* than the Mac??? You lost me there. The Mac's not perfect (play with one for an hour and you'll see). For example, you could make the drop-down menus come down automatically when you move the cursor on them, then go away when you move the cursor off (rather than waiting for a mouse click). "Apple has tough lawyers" is no justification for sloppy software design.

I think you have totally missed the point of Eric's message. I think what he was saying is that the Atari is a LOT of machine. It's *much* nicer than a PC, and it's *much* nicer than a Mac, "hardwarewise". So why don't they get their act together and design some good software? Personally, I like the machine; I just think it has tremendous potential for improvement. You can either sell a raw machine or an ergonomically designed product; looks like the Atari hit the left end of this spectrum.

While we're on the subject, here's another design question I've been wondering about. The screen redraw algorithm seems to be completely brainwashed. Consider this: you have three windows open, say, on drives A, B, and D. You have only one physical drive, so it's doubling both as A and B. D is your ramdisk. Now you double-click on a file and go through the silly show/print/cancel dialog box to see it on the screen (why not just use a GEM window?). Now comes the fun part. The file ends, it tries redraws your screen. First it redraws the outline of the lowermost window (say, D). Now it makes you insert disk B in drive A, and redraws the outline of the B window. Next, you insert disk A in drive A, and it redraws the outline of the A window. Now it fills in the D window, and then the B window, and then the A window. Even without the disk change operation, this process takes several seconds, and results several rewrites of parts of your screen. Slow and annoying. There is NO reason to do this (our unmentionable competitor redraws the screen almost instantaneously). The OS doesn't check that you inserted the correct disk for B (i.e., the same disk it expected), nor does

it care if you insert a different disk for B when you get down to using B again. So why does it need to read the disk (slow, slow) when it redraws the screen?

If you really care about consistency of the window with the current disk in the drive (and it isn't obvious that you need to in all cases), it is easy to detect whether the user has ejected/reinserted a disk. In fact, you could easily update an open window automatically if the user changes a disk.

These aren't flames or complaints or "why did I buy this machine?" rantings; I'm only suggesting that with a little bit of thought, Atari can improve its desktop and user interface considerably *without* running over the Mac's copyrights. Why isn't there a MOVE operation, only a COPY? Why can't you rename folders? Why is file renaming hidden away in SHOW INFO? Why only four windows? Why use such an immutably large font in the windows (with broad scroll bars), thereby making what is really a larger screen than the Macs have look like it has much less space on it? Why make us adjust the volume of the monitor *every* time you turn it on, rather than saving it in DESKTOP.INF? There are several things in their design that could do with some polishing. And then there are several things that they didn't even think of. How about using the right mouse button as a way of getting help on a particular menu item while it is lit? Or even the HELP key? Even the Mac doesn't do this. I have a million *constructive* ideas if anyone wants to listen, and I'm sure anyone who has used the Atari for more than a day has a million of his/her own.

This isn't, of course, an issue of Atari vs. Mac. In fact, if they don't try to copy the Mac, they should be able to come up with something *better* than the Mac. (And then it'll be their turn to hire tough lawyers :-)).

Uh oh, it's the CPU wars again...[Warning -- 68000 partisan]

It seems to me that the 68030, not the 68020, competes with the '386. Isn't
this right? Intel seems proud of the fact that they have arrived first in
the market at each 'generation' (8086 vs. 68000, 80286 vs. 68020, 80386 vs.
68030). But what do they think of the relative power of the competing
devices? I note that Commodore Amiga (and other vendors) sell software
emulators for the 8086 that have reasonable performance on the 68000. What
about this? What about relative floating point performance of the
comparable chips when an application cannot afford the expensive 8087
coprocessor? What about the disastrous tradeoffs that must be made when a

program must access large data arrays? Even the lowly 68010 could operate in a true virtual memory environment, but Intel has only recently arrived at this performance level.

Now I agree that Mot. has jumped the gun substantially in their announcement of the 68030, and are therefore sinking to a rather low level of marketing. They join another company at that level, one who has a longstanding reputation for bogus benchmarks, late deliveries, non-functional production silicon, and offensive marketing.

[I am affiliated with neither Intel nor Motorola. Opinions are my own.]

>tom johnson   inhp4!ut-sally!oakhill!tomj

The 68020 (and presumably, the 030) has input lines asking the external device (memory, peripheral, etc) how wide it is. That way the processor can ask for a long from a byte-wide device and do 4 reads after the device says "but I'm only a little bitty byte wide". But I would be frightened away from an architecture where a true 32 bit processor has byte-wide main memory. Still, you build the machine with the fastest memory you can afford, and if it ain't fast enough, use wait states. Faster processor speed is still significant, especially in a processor with an on-chip cache. Remember: memory halfs in cost and doubles in speed every n years (where n used to be 5, and seems to be approaching 1). I realize there is a theoretical limit, until we all wise up and start using transphasors (transistors that switch laser light).

This brings up an interesting point. In the mid-70's, everyone started making processors with MORE instructions that do MORE processing each. This was, in part, due to memory bandwidth limitations. The new genre of RISC machines is going exactly the other way: processors with FEWER instructions, each of which does LESS processing, because memory bandwidth has improved. The RISC concept allows more specific manipulation of processing power (and therefore requires more intelligent compilers, to take advantage of the quantization of the processing unit). When's the 78000 due out?

-Eric

Summary: Why not use the graphics routines in ROM?

[]

I don't see why an ST implementation of OS9 couldn't include access
to the GEM graphics routines (VDI, and perhaps parts of AES). These
are in ROM anyway, might as well use them, or allow OS9 programs to
use them. (Portability? Ever tried running a graphics program on
an 'IBM-compatible' just to find out you've got the wrong graphics
card? 'Compatibility' is a myth!)

     I'm working on porting an assembler/linker to the ST, but
I can't seem to find a description of the .PRG file format. What
goes in the header - what does the file have to have to be loaded by
the GEMDOS loader? Any specifics or directions to specific parts of
the developer's documentation would be most appreciated. I will
make this assembler/linker available when it is finished.

Once again, I apologize for starting this flaming session by not being clear what was on the disks I bought. The $40 bought four disks:

1) System/Finder
2) FreeTerm/Red Ryder
3) BMUG 9.blah (Some demos from the Boston Macintosh User's Group)
4) BMUG 14.blah (More demos from BMUG)

I assumed I was paying for the System/Finder, four blank diskettes, and the effort to make copies of the software, and that I am on my own for the shareware.

Alex Leavens did not try to mislead me about what I was buying. I assume rather than I know, because I didn't specifically asked. Everyone in the booth was open and honest about all questions I did ask.

Marty

This weekend I was able to drag a 'real' MacIntosh home and hook it up to my Atari. Although I was able to transfer a lot of data between the machines using Kermit, I was unable to successfully use the Magic Sac 'transmit' program to move data between the machines.

The typical result was that both sides would start up correctly, the Macintosh side would reach the 'Waiting for the ST' prompt, and the Atari side would count backwards 987654321 and never get to the 0. This would always happened on the first transfer, except for once when I managed to transfer an entire diskette, which however turned out to be unusable.

Current status:

1) transmit program doesn't work with either Macintosh or Lisa
2) known bug in kernel prevents telecommunications programs from working
3) bug in Apple code prevents single drive systems from doing disk to disk copies.

I haven't tried to call Data Pacific again, and I haven't received an updated diskette from them, nor have I heard anything at all back from Alex Leavens about new copies of the diskettes I bought from him.

I would appreciate hearing from ANYONE who has had success with the transmit program; it's still posssible that my problem was with a bad copy of the utility.

Of course, there is no comparison between the two classes of machines, because you in here introduce more than two classes of machines. I would not put Sun workstations and Turbo Amigas in the same class of machine simply because the Amiga does not support any kind of memory management. If you want to have a grown-up machine, one that supports multi-user/multi-tasking you really need to have this. I have used 68k boxes without that have tried to do it, and it works, but you are just asking for trouble. That the same 286-based box can support an unprotected os like ms-dos and a protected os like Unix means that it can function in either of these two classes. Not until you have the 68030, or you make an entire subsystem plug in with a 68020 and an mmu, can you claim to have upgraded your Amiga the way plugging a 286 upgrades a pc.

>   Another important point to make is that operating systems implemented on

>been floating around for at least 3 or more years. To compare the 80386

In the first place, msdos, while not taking advantage of the functionality of the 286 or the 386, is certainly not a kludge when run on them. In addition, when you go from one type of 68* based box to another, you also need to rewrite the operating system, because the memory management systems are incompatible. People have also generated 286-based cards that plug into plain old IBM pcs and have gained a significant performance upgrade, while running their old software. I'm sure the same thing can and will happen with the 386. And Unix implementations for 8086-based chips have been floating around for at least 5 years. MS-DOS already is a 16-bit os, and always has been. When going from a 68020 to a 68030, you will have to rewrite the os to take advantage of the memory management that the 68030 provides...otherwise you just have a little faster 68020, much like you can use a 286 as a faster 8086. How about if we compare apples to apples? Can you say "incoherency?"

>P.S. BTW, have you guys heard about the 78000 (!?) See Nanobytes in

>and GEM goodbye (I think). And as you say, I doubt OS9 has the libraries.
>Now, weather the ST version of OS9 has a SIMILAR type of windowing and
>menu system... I don't know, havn't seen the ST version, and I don't know
>how far it has gotten in it's evolution. Comments anyone?

I've been using OS-9 68K on the Atari for few days now (a week?)
and it's quite good, but doesn't currently have a GEM-like interface.
Rather, the /term emulates a Televideo 925 (not knowing much about
that particular terminal I can't say whether it's a complete emulation,
but I doubt it). The RESET vector does not seem to be affected by
OS-9. At least, if you reboot, you do so all the way back to GEM.
This is very inconvenient for a floppy disk system, but for a
Hard disk user it won't have much consequence. It does seem, however,
that GEM is still around if you can figure out a way to get at it.
I'm guessing in this much, but you never know till you try.

Cheers! -- Jim O.

     Actually, it isn't possible to detect a disk eject in all cases, as a result of a hardware failing. Apparently, the machine cannot detect an eject if the diskette is write protected.

     This leads to a problem in Magic Sac, which requires the occasional use of function keys F1 and F2 to tell the Atari that the diskette is to be (or has been) ejected, so that the Mac Emulator will do the right thing.

Apropos the issue of what sort of multitasking operating/windowing system, GEM-based or otherwise, one would like to see on the new generation of Atari machines, this week's _Infoworld_, in a highly enthusiastic review of Simultask for the AT&T 6300 Plus, describes a few essential features:

"With Simultask, AT&T has pulled off an amazing stunt: This system runs Unix System V and offers MS-DOS as a task under Unix. What is amazing is that the MS-DOS task is as capable, compatible, and speedy as it is. MS-DOS in Simultask runs MS-DOS programs with the speed and compatibility of any 6-MHz PC AT compatible. In one instance, we found Simultask's MS-DOS more PC compatible than running MS-DOS directly....

"The AT&T 6300 Plus running Simultask offers an elegant one-box solution for those wishing to access both Unix and MS-DOS. You can use binary information in either environment with ease, and text information is easily converted from MS-DOS format to Unix and back."

Question: has anyone on the list taken a close look at Simultask? The review remarks that Simultask runs within an (apparently windowing) interface/shell called PC 6300 Plus Office that is somewhat slower than Microsoft Windows and Desqview, and not quite as sophisticated as the AT&T 7300 user interface. How does this interface compare with the Mac/GEM style of windowing? Is it a suitable model for a 4-meg multitasking Atari?

On a related topic: is anyone on the list aware of any recent research reports or studies which exhaustively compare, contrast, and evaluate the features of currently available windowing systems (X, Xerox, Sun, Symbolics, Microsoft, Macintosh, GEM, etc.)?

>really fair to compare that which Intel has now with what Motorola will have
>in a year. A more fair comparison is between the 68020 and the 80386.

To say that Compaq has "released" an 80386 based computer is stretching
things a bit too, don't you think. They announced it, but said it would
be available after January. This is similar to what Motorola announced.
By the way, IBM is said to be readying an announcment in January for
their 80386 based machine, which will be available in June. And don't
forget that a multitasking operating system won't be available until
around June either. Until then, these 80386 machines are just big
fast PC's. Meanwhile, Apple is readying a 68020 based machine for
release early next year.

Isn't vaporware fun!

In case anybody's forgotten, there is a newsgroup called

     'net.micro.68k'

Why don't we all stop posting to multiple newsgroups and just post to
that. If you want to continue this line of thought, it's the ONLY
thing happenning on net.micro.68k right now.

                        -Matt

(I do admit to multiple postings early in the conv, but it's gone on
 too long for my tastes). This is of course, my opinion.

I work in France, but would like to use the developer's kit distributed in the

US, partly because I suspect it'll be more up-to-date than its French peer, and mainly because I'd rather use the same documents as everybody else on this net.

If somebody from Atari is reading this (the ubiquitous Neil Harris ?), maybe he/she can tell me if there's anything that says I can't do that (e.g. register as a developer in the US and develop in France). If there isn't, I would greatly appreciate an address (on my knees for a Telex number), pricing data ($300 + shipping ?) and an account number of some sort (to send the money to; wouldn't be personal money, the order would go through a company).

Help, this is urgent, my 1040 needs it !

Technical Q.: is it possible to bypass all the sound generation hardware on the Yamaha chip, and access directly the D/A converter ? If so, at which addresses do the appropriate registers live ?

Marty,
Could you please specify the MAC ROM part numbers needed for the MAC Emulator.

I would like to check on availability before buying the board. Thanks,

I got one of the ATARI hardisks (SH204) yesterday (the price for the SH204
has gone down from SFr 2190.- ($1290) to SFr 1490.- ($880) list price in the
last month (I payed SFr 1290.- ($760)).I spent most of the night
playing around with it and naturally :-) have some questions:

- How do you invoke the 40 subdirectory "feature" realiably?
  Do you actually have to open 40 subdirectorys? I had a total
  of 80 subdirectorys (not at one time) on the desktop last
  night and didn't notice any ill effects. This morning I did
  experience the bug after copying a lot of stuff from the
  harddisk to floppy (I didn't have any files in partition D:
  anymore), but I didn't count how many subdirectorys I had
  actually handled.
- The german handbook doesn't have a warning about having more
  than 40 subdirectorys in it (I have seen a US handbook and
  the rest of the german hanbook seems to be a one to one
  translation). Does this mean that the bug was fixed for
  german TOS or is the upper limit just higher? (I wonder
  what the legal implications of this is, if I trash my harddisk
  due to the bug?)
- Has anyone seen or used a backup program (PD or commercial)?
- Does anybody have a program like TREE (MS-DOS)?

BTW I would like chkdsk too, if its not too much trouble.

This isn't true. The Prodigy 4, a Mac running a 16 MHz 68020 w/68881 FPC
works just fine. Some things want to run with the cache off (because they
contain self-modifying code). I'm not sure whether the 128K Mac ROMs are
a requirement for this, but, most definitely, the Mac WILL RUN ON A 68020.

I picked up Regent Base also and have the same feelings as to the
manual,I've called them quite often and have been able to talk to
Frank,He's been most helful, and all of the time it's been my fault. It
is very powerful and makes very good use of gem. I think it's like a
"Rbase 5000"clone almost.They are working on a tutor program and this
should help alot. As it stands I would Highly recommend this product if
you "RTM" several times, very very carefuly.For customer support you
might call all during the day.I WONDER DOES IT MATTER THAT I LIVE ONLY A
FEW MILES AWAY.

I don't know for sure what they use, but the Western Digital 33C93 chip

looks like an almost perfect match. Does anybody else know how close
the driver, etc are? I also forgot to ask the price.

Here's a technical question about systems software. When we
change what the mouse looks like (mous_form), the keyboard
doesn't work for a while, until 6 or 7 keystrokes have been
entered. Any ideas why? Any ideas of a workaround?

code fragment:

```
main()
{
int     handle  ;
        appl_init();
        v_opnvwk( work_in, &handle, work_out  ) ;

                graf_mouse(3, OL) ;
                Cconin() ;

                for (;;)
                        {
                        if (Cconis() != 0)
                                {
                                printf("have a key\n") ;
                                Cconin() ;
                                }
                        graf_mouse(255, mous_form) ;
                        }
        v_clsvwk(handle);
        appl_exit();
}
```

Thanks for any ideas...

I too recently purchase a copy of Regent Base with the hopes of using it to maintain mailing list, etc.

I first tried to use some of the example programmes supplied on the disc and quickly ran into problems. I tried for 5 evenings to work around the problems and evenutally wrote a 5 page letter to Regent Software, Attn. Frank Cohen. About two days later I received a phone call from Mr. Cohen thanking me for my letter and he preceeded to answer each of my questions or problems I itemised in the letter.

In short Regent Base has a long way to go before it's very useful. I feel that, for myself, my money would have been better spent on dinner.

For those of you who want detailed information, I've included parts of my letter to him and I've tried to recall each of his answers.

No Sequel Editor Documentation:
I have the documentation for V1.0 and although it does discuss some of the things in the Forms Editor, there is no documentation for the Sequel Editor. In spite of this, I have been able to use it as it is very similar to the Procedure Editor in the Forms Editor.

Note: Sequel is the language in which you write your database programmes. It's like the language BASIC, sans flow control statements except for a sort-of GO TO. Regent Base comes with two types of editors, Sequel and Forms. The Forms editor is used to construct a GEM screen format and the Sequel editor is used to construct your database programmes. All the editors are very primitive.

Apparently the software was release without any documentation for the Sequel Editor and the manual is being rewritten.

Sequel Editor long line bug:
Enter a line of characters almost extending the full width of the screen. Now move to the middle or beginning of that line. Press the INSERT key repeatedly until the previously typed characters move off the right edge of the screen. Now press the DELETE key to erase those inserted blank characters. After a while you will notice that there is an infinite source of characters from the right edge of the screen -- far more than you originally typed in.

There are many bugs in the two Sequel editors and they are being fixed or worked around. I expressed my displeasure of having to learn another editor in order to create my Regent Base programmes and I asked how I could create my progammes using another editor (emacs). He said it was just an ascii text file and I could use any editor to create my programmes. I'm doubt if he has tried this as I found that if you saved a programme using the Sequel editor(s) the files had formatting characters or something in them. It wasn't as straight forward as I hoped.

Sequel Editor can't write to other disc:
Select the "Save Form" option from the drop-down menu. Enter pathname of another disc, for example D:\FOO. The editor will display an alert box with the message "Path not found".

One of the bugs to be repaired.

Forms Editor cancel bug:
You can crash the Forms Editor by entering the Forms Editor from MENU.PRG. Select the Procedure Editor from the drop down menu. Select the "Save Procedure" item from the drop down menu. Select the cancel button on the resulting dialogue Box. Watch 2 bombs appear on your screen.

One of the bugs to be repaired.

Forms Editor can't close window bug:
Start the Forms Editor from the main programme MENU.PRG. The Forms Editor starts-up with an empty window. Select the close box -- the window will not close. Now move the mouse onto the menu bar causing a menu to dropped down, and then deselect the drop-down menu by pressing a mouse button outside of the menu. Now press the close box on the window -- the window closes.

A bug in GEM (?)

Dialogue box bug:

In the dialogue boxes in the Forms Editor used to name files, you can create a file with a colon ':' in it, such as A:FOO. This creates the file 'A:FOO' on the default disc (bug). Other programmes cannot find this file because the ':' is often interpreted as a delimiter and not part of the filename.

> Apparently Regent Software has there own set of dialogue boxes rather than the ones supplied in GEM. He said they would be using the GEM dialogue boxes in the future.

Return Address bug in MAILRPT.FRM:
The line that determines the return address from the MAILLIST.TBL should be changed from NAME^"MYADDRESS" to NAME="MYADDRESS".

> The ^ operator means "like" when matching two strings. The "like" operator will match the null string. I think this is a bug but Mr. Cohen wasn't convinced.

Sorting problem:
I attempted to use the sort programme as described in the documentation and consistently had trouble. I enter data into the MAILLIST.TBL via the entry form and then I return to the mail menu and select the SORT item. The sort programme displays it dialogue box and I enter the file MAILLIST as the database to sort and then I enter fields NAME, SORT1, SORT2 and then I select the option to begin sorting. The programme then displays its activity box and it counts up for a ways then then display and error message:
"That field does not exist" and stops.

> The sort programme doesn't work correctly on a 1040ST. It's also slow. Mr. Cohen said it's being rewritten.

Some MAILRPT.FRM options do not work:
When I use the PHONE BOOK or Federal Express Label printer options from the report form I get a "Can't tab backwards" error.

> I didn't really get a good answer on this. Apparently the message occurs when a previous string is longer than the field it uses.

"OUTPUT TO" cannot use the modem port:
Currently the Regent Base OUTPUT TO directive cannot output to the modem port on the ST. I need to output to the modem port as I don't use a printer connected to the ST but rather another computer. The CONTROL.ACC desk accessory allows the user to indicate that the system printer is either on the printer port or on the modem port.

> This was my biggest complaint. In future versions provision will be made to output to the modem port.

Form Editor labels are unreadable:
When displaying the labels of items in a Form by selecting the Show Labels option from the menu, the labels are draw in such a way that they overlap or they are off of the screen.

Future versions will have the labels display inside of their corresponding fields.

The documentation indicates there is limited space in the Regent Base Sequel Editor or Procedure editor for programme text (I think it was 8 pages or so). Consequently Regent Base programmes are all scrunched up and not very easy to read. Is that limitation (8 pages of programme text) also present in the Regent Base interpretor ?

The limit in the interpretor is 64K of text. The 8 page limit is in the editors only.

The font used in the Sequel and Procedure editors editors is ugly.
How can I change that font to a different font or to the system font ?

The font is a DEGAS font file SYSTEM.FNT. I tried to replace it with another font but it didn't work.

I have a program that generates MAKEFILEs for Modula-2 programs and would like to distribute it, but I do not have a way to SHARify my modules. Would someone send me a shell script or c program that generates a SHAR file?

Thanks.

*** ccccccccchhhhhhhhhhhhhoooooooooooommmmmmmmmmmpppppppppp ***

Hi. I'm posting this separate from my mail request to try and avoid confusion.

I have paid for, and am waiting for my 1040ST (should be under a week, I'm staying awake at nights!). Congratulations all you out there who have one! I bought mine after 4 months of fairly intense research into the computer market and I think it's the best thing around (high praise from me, a picky SOB). So, I'm about to set up shop, and I have a few questions that maybe someone can help me with. Here goes:

1) I like the keyboard for the IBM AT better than the 1040's. Is there any way I can make a plug that allows an AT keyboard to be connected through a hole in the case, while still retaining the mouse/joystick ports? (I don't even know if the AT keyboard will work in any way w/ the Atari)

2) Can anyone give me any information about the vaguely rumored Microsoft word processor (Write?), like if it's a copy of Word, and when it will come out?

3) I saw earlier an article posted by a man who had rigged a box to change the color display to monochrone (I think this is what it was). How is this done, and is it intensely complicated?

4) Has anyone heard anything about 2, 3, or 4 meg upgrades for the 1040? I'm not sure if it is possible (room on board) but there are 1 meg chips out now.

5) Was the RAMdisk/hard drive problem ever solved?

6) (controversy time) Which is the best C?

7) Is there a mutlitasking, GEM-like (meaning mouse and windows) environment out there? Or will we have to wait for DRI's GEM?

8) If we must wait for the new GEM, how will we use it? Replacing ROMS, using it in memory (yech!), etc?

9) What is the Arpa public domain library and how do I access it?

10) Does anyone have the CP/M emulator out there? How fast
is it? Does it emulate Kaypro (ADM-3a) video? Does it work
for everything? Is it Z80 or 8080?

and finally,

11) What games do people like out there (and why).

To avoid much stuff on the net, please use E-mail to answer the last question.

Thanks for any information you can give. Atari forever!

Well I like alot of desk ACC'S so I have to upgrade the memory on my 520ST with Tos in Rom, I know that theres many ways of doing it,Whats the best and easy way using my own chips???,also someone had mentioned something about using 1Meg chips.
Maybe I should do the clock thing while its apart. Thanks for any info

hardly. They are advertised, and are being sold, at least in this area
by Businessland, Computerland, and Fry's. Talking to salesmen at the
stores, they are going like hotcakes, but they are getting them in, and
selling them to real-live people.

This is a question which can only be answered by "the voice of Atari"
concerning the for-retail-sale documentation that was expected to be
available around the end of the year.

Does this documentation make the documentation of the developer's kit
redundant? I need documentation of everything from the programmer's
interface to GEM and TOS down to the magic hardware addresses and
disk formats. If the "Table of Contents" of these books (I assume
there will be at least 4) could be distributed here, it would help
making decisions about whether to wait another 3 months or not.

If the retail documentation does NOT cover all of this stuff, I'm going
to (have to) pay the $50 to become a registered developer and the $300
for the developer's kit. However, except for the documentation, I
don't especially want or need anything in the developer's kit.

I realize the developer's kit has lots of tools and software. I am
working primarily with Mark William's C and OS-9, so most of those
tools aren't very helpful. Most of the rest, I can write myself. (I
wrote over 60,000 lines of software this year; a little work doesn't
bother me)

As a recent (proud!) new owner of a 520ST (mono, 2SS drives for $570 from
47th St Photo) I have a couple of questions concerning the PD stuff in
the Subject line. Especially, does an error during a Kermit file transfer
indicate a bad file on the receiving end, or does it just mean that the
program had to retry a couple of times to get the packet, but it did get
it okay finally? Thanks for any comments. BTW, I'm typing this message
onto my host from home via the VT52 acc.

From: Stuart Friedberg <stuart>

I have had a monochrome 1040ST on order through my local dealer since
the end of July. From reading this newsgroup it was clear that 1040's
are scarce all over, so I refrained from flaming Atari or flaming my
dealer. I simply assumed that production could not keep up with
demand.

However, my dealer got fed up with having a machine on order for two
and a half months. In addition to my machine, the store paid for 20
machines and received none of them. 520's are coming in months after
being paid for. 1040's aren't coming in at all. For this reason, the
two store managers and the branch manager had a full day "chat" with
the appropriate Atari representative. They were unhappy and the rep
left, ah, uncomfortable. The statements in this paragraph are facts.

I am now going to relate some statements that I can not confirm
personally. Treat them as rumor, but notice that I have signed this
message. There are no 1040's in the warehouse. There are no 1040's in

production. Atari has been accepting orders, and payment, in order to
build up liquid assets. I have heard two conjectured motivations:
(1) build up capital for production facilities, and (2) buy Commodore.
I choose not to speculate, but these statements are consistent with
the observed facts.

In my opinion, the ST is an extremely competent machine at an
unbeatable price. However, it doesn't make any difference what the
price is, if no machines are available. Whether the statements of the
preceding paragraph are true or false, it remains true that the dealer
has my money, and Atari has the dealer's money, and Atari is not
delivering. This is not responsive and borders on irresponsible.

Has anybody (even at Atari) thought about how hard (or easy) it would be to
add a second Yamaha sound chip to an ST (perhaps externally, via the cartridge
port with a few additional address wires) to give 6 voices and the possibility
of stereo? What little fooling around with music I have done suggests that
three voices is just not enough for serious work and 4 is just barely enough.
But 6 would be very useable.

                    (char *)NULL,
                    (struct line *)NULL,
                    (time_t)0,
                    (uchar)0
                    };
```

I have been unable to get the program working. The program exits with a "no memory for macro" error and the touch program "touches" all files back to the date that TOS was born (i.e. midnight sometime in November 1985). So question one is, "has anyone other than those at CASE gotten this program to work?"

My second question has to do with the last cast in the structure initializer. Here's the scenario. My dev pack has been ordered and should arrive next week, so I compiled the code with the CP/M-68K compiler (which is identical to the early ST version right down to the serial numbers). I had a friend compile it on the ST with his DEV pack and he got the same errors. The early Alcyon compiler only supports unsigned ints, so uchar is defined as char in a header file.

But the code parser (c068) balks at the coercion with the error "invalid initializer" which means I tried to init a variable with something other than a constant. Even the cast (char)'\0' got the same error. Now I know the last element of that structure has to be a character constant or the structure will not be filled properly.

The code generated for a structure like this goes ahead and fills the remainder of the space to allign on a word boundary, but the size of the last element determines how that element will actually be stored and accessed. Structure initialization and size has been a known bug in the Alcyon compiler at least since 1983. One problem with this structure is that all of the beginning elements are 32 bits long. Alcyon has trouble, and always had, with structures or function parameter lists that all have the same (long) size.

Another minor beef. If you

```
#define uchar char
```

Sometines the preprocessor has trouble in an expansion that involves a cast. If you

```
#define void
```

casts again can lead to difficult to track errors. Is there a reason to avoid typedef in these situations? Why not use

```
typedef uchar char;
typedef void int;  /* after all Alcyon expects int returns by default */
                   /* even when none are specified.  Check the stack */
                   /* popping code it produces after a jsr */
```

Defines are hard to track down in a preprocessor output file because they all dissapear. But a typedef follows through that output, and you can see what a cast or value is. DRI used to

```
#define FILE struct _iobuf
```

That made a file definition bug a real bear to find. However,

```
typedef FILE struct _iobuf;
```

is more logical and closer to the intentention of using FILE structures in the first place.

While I'm on the DRI soapbox. I compared the AR68 output for gemlib to that for the old clib libraries (is AR68 available for the ST yet?). The modules are practically identical in fact the object code from CP/M-68K ports directly! So much for "the only similarities between these two systems (GEM-DOS and CP/M) are superficial." BTW Concurrent DOS is on the market for the 68010 according to a Concurrent PC-DOS OEM I know and a CP/M-68K OEM I've contacted. He said DRI wanted too much for the port.

I've beat the CPM drum in this newsgroup before and gotten flamed, but
I recommend that anyone who writes software or is trying to port
software for the ST look at as much CPM code as possible. There
really is a world of good programs out there that require very little
effort to move to the ST. It's ridiculous that there's no equivalent
to "real" xmodem i.e 1024 packets, true CRC, batch files, 19200 baud,
scripts, etc. in the ST PD library. 19200 is great for moving files
between the ST and your other computer, whatever that may be.

   Is there anybody out there who uses TVX/VI who isn't having problems
with it? Three ST owners at this computing center have a copy (from the
same "original"), and we all have found it to have a fatal flaw. Two of
us encountered errors where the editor would die (losing all changes) while
scrolling up or down. The third person, hearing about this, started doing
periodic writes while editing. Well, when *his* edit session bombed, it
turns out that the previous 'n' writes had put garbage in his file. So
we all went back to using the primitive yet functional Metacomco editor
(which, by the way, has a limit to the size of file it can edit-- I haven't
run into the problem, but another guy has). At any rate, if anyone has
had a similar problem and fixed it, I'd appreciate hearing about it;
conversely, if people have been using it with no problems, I'd like to hear
about that, too. Looking into the problem myself is in my queue, but

it's a ways down there, and days are too short for me to get to everything
I want to do in a finite amount of time (>- sigh! -<).

Keywords: RAM DISK patch reset HD RAMdisk Hard Disk SM

Well after a bit of digging and disassembly my brother (a sharp troop) found the correct combination to get the reset surviving RAM disk to play as drive F: in a HD system (Atari 20meg). I don't have the code right now handy but will post it this weekend (the hex file again or uuencoded). In essence the patch was applied to two places. First, as was mentioned before on this news group you need to change the bit set in the 'drivebits' variable down in low memory. The BSET #3,d0 needs to be BSET #5,d0 (for drive F:). The other patch is applied to the compare instruction in the code that is executed when RWABS calls the RAM Disk.   The RAM disk checks the device number and if it's not the right number it passes control through a JMP instruction to the Hard disk vector the RAM disk saved at boot time. As I said I can't remember off the top of my head what the exect CMP instruction is and what it must be changed to, but you should be able to find it. If not, just wait for the posting. The above patches imply that the RAM disk need be executed after the hard disk driver is installed, so it may take over and save the hard disk vectors.

Anyways they are both living happily in the system. 1 360k drive A:, 1 720k drive B:, 1 4meg drive C:, 1 6meg drive D:, 1 10meg drive E:, and 1 500k drive F:. Veerrrry Niiice!

The following was posted some time ago by J. R. Bammi via J. M. Turner:

-- cut here --

I extracted the following info. from documents that came with the development system. I have only found the .prg (output of relmod) format, and not the .o format. The input of relmod is the standard cp/m-68K relocatable files, so I guess the .o format is the same as for cp/m-68K. I am not at all familiar with cp/m-68K, and i could not find anyting in the documents I have about the format of .o files. Maybe you are familiar with cp/m-68k or have access to the relevant cp/m-68k documents. Looking forward to your PD diss assmebler.

The format for a .prg file is as Follows (word = 16 bits). Output of relmod - 16 bit relocatable objects are not supported by Gem Dos.

14 Word Header
Text Segment Image
Data Segment Image
Symbol Table (Optional)
Relocation Info (Optional)

Header Format:

Byte	Size(words)	Contents
0	1	Contains 601A H Denoting Contiguous text, data and block storage segments
2	2	Size of Text Segment - Bytes
6	2	Size of Data Segment - Bytes
10	2	Size of Block Storage Segment - Bytes
14	2	Size of Symbol Table - Bytes
18	2	Reserved - Always Zero
22	2	Reserved - Always Zero (This is supposed to contain the Begining of the Text Segment and execution, but execution always begins at the top of the Text segement, hence 0)
26	1	If Zero then Relocation info IS present, No relocation info otherwise. Always Zero for Gem Dos.

Symbol Table Format:

Each entry is 7 words.

Byte	Size(words)	Contents
0	4	Name - zero padded to 8 characters
8	1	Type
10	2	Value

Type	Value
defined	8000 H

```
equated       4000 H
global        2000 H
equated register   1000 H
external reference  800 H
data based reloc.   400 H
text based reloc.   200 H
bss  based reloc.   100 H

where:
  reloc. == relocatable
```

A symbol with multiple characteristics has the bits OR'ed in the type field.

The value field is the value of the symbol (address, register number, value of an expression or some other value). When the value field is non-zero AND the type field contains an External Symbol, the linker interprets the value to be a common region in which the size of the region is the value in the value field. Multiple such entries may be present and the size of the common that the linker ultimately decides on, is the greatest of the values, of the same name.

The nm68 utility provided with the development system can be used to dump the symbol table.

Relocation Information:

If the last word in the header is Zero the relocation info is present in the following format: (following symbol table if present)

Byte	Size (BYTES)	Contents
0	4	Offset from the beginning of the Text Segment of the first longword needing relocation.
4	1	Relocation offset byte
5	1	" " "
.....		
xx	1	A byte containing Zero terminates

Relocation offset byte - Gives the offset to the Next longword in the Text Segment to relocate (offset from the First Offset) and so on. When an offset of Zero is encountered the relocation info is terminated. The bytes of Relocation offset give succeeding offsets. (so the smallest legal value is 4 (size of long word)). If a succeeding offset is greater than 254, then a byte containg One (1) will be encountered, signifying add 254 to the previous total.

I hope that I explained the above clearly. I guess an example is appropriate to say what i mean.

Suppose that the first longword to be relocated is at offset 128 from the begining of the text segment. The next one is at offset 132 from the begining. The next is at offset 390 from the begining

of the text segment (ie. 258 bytes from the second longword to be
relocated), Then the relocation info looks like

```
    byte Size(BYTES)   Contents
    0    4         128
    4    1         4
    5    1         1    (add 254)
    6    1         4    (128 + 4 + 254 + 4 = 390)

    and so on.
```

-- cut here --

```

Obviously, Atari cannot meet the demand for 1040's. (the machines, not
the forms :-) And it IS trying to raise capital (e.g. the "going public").
But to hold on to peoples' money is not only immoral (illegal?) but also
against Atari's interest. I assume they 1040's sold were sold at a profit.
I also assume the factories involved still exist. So the only thing gained
by the (rumored) witholding of that production capacity is bad PR.

Osborne went belly-up because of the early announcment of the Osborne 2,
prompting consumers to wait and avoid buying the 1. Atari has announced

the 2080 and 4160. Are they trying to discontinue the 1040? Are they
trying to FORCE the consumers to wait for those? I think that would be
a grave mistake: There IS a market for the 1040, obviously! 1 megabyte
is enough for a LOT of uses, and the larger RAM chips are going to be
very expensive for some time to come. 512K is NOT enough for any sort
of development work, as the demand for upgrades proves. And by 'development'
I mean 'programming', not necessarily commercial. The "nobody programs
besides the professionals" myth has been shattered by the sale of
hundreds of thousands of copies of Turbo Pascal.

Please, Atari: let us have 1040's!

Summary: Mac cartridge success

I know someone who has had no real problems transferring disks from a
a 128K Mac to an ST. The last letter I got mentioned that the transfer
program has had some problems running on a Mac Plus, and that they now
had an update available to people who needed it.

Also, the latest update (version 2) does seem to handle the serial port
correctly; "freeterm" 1.8 seems to run fine.

Keywords: Atari C-source
Summary: C++ commercial support
Xref: mnetor net.lang.c++:361 net.micro.atari16:2409

Oasys Systems has been advertising commercial support for C++ in a variety
of systems; in particular using Lattice C on the IBM PC.

It would be relatively simple bring up C++ under Lattice C for the ST;
Oasys just has to be convinced that it is worth the effort to do so.

None of the other ST C compilers (especially Alcyon C which comes with the

developers kit) would be usable back-ends for C++; the backend compiler
the AT&T released C++ frontend REALLY!!! needs at least 32 significant
characters in names. To my knowledge, Lattice C (using the GST linker)
is the only ST C compiler that can support 32 significant characters in names.

Summary: Two great processors
Xref: mnetor net.micro.68k:1362 net.micro.amiga:5145 net.micro.atari16:2373
net.micro.mac:7468

The continuing debate on the relative merits of the MC68030 / 80386 seems to
be a bit pointless. The computer industry is famous for the speed at which
equipment is designed, introduced, used and falls obsolete. Of course
Motorola's product is superior to the 80386 because there is an almost
1.5 year difference in technology. Doubtless the 80486 (which is probably
under development right now) will be superior to the MC68030. What most
people seem to forget is that processors are chosen for a particular
product for a variety of reasons, only one of which is their programming
characteristics. Interfacing requirements, # of support chips, price,
etc. are all important characteristics for a manufacturer. I'm sure that
for given applications either Motorola or Intel win. Instead of these
pointless `A is > B because B is built by 3 toed sloths' arguments, why
not try to restrict postings to actual specific comparisons between the
two or information which may not yet be generally known.

I am looking for a public domain version of the "make" program
which will work on a VAX running VMS.
If no one has such a beast, then I will hack any supplied version
which is written in C.

Thanks for all respones,

Jerry Zarycky

FLAME ON
&*&^$####
FLAME OFF

It takes me an ungodly amount of time to download and uudecode programs
posted or mailed. I know it is my problem to deal with, but I believe
we could all benefit from a few lines concerning program limitations.
For instance: The program only works with monchrome monitors; or TOS
MUST be in RAM not rom, or the other way around; Must be the first
program in the AUTO folder; etc.

I was REALLY looking forward to speedy disk access. My TOS is in ROM...

I remember that a while ago Neil Harris said that Atari Explorer would
be published in July, well it's now October and no Atari Explorer.
What's happening with it? Is it still going to be "Atari's Vioce?"

I flamed about lack of hardware limitations for posted programs. I
specifically mentioned the speedy disk I/O program. My mistake.
Somehow, in my excitement, I overlooked the RAM in "RAM TOS boot disk"
included in the readme doc.

I apologize to the author and to the net.

In article <861006-042116-3507@Xerox> Ulrich.wbst@XEROX.COM writes:
-Balma and Fitler's book contains references to three Gem Functions that
-are available on the IBM version of Gem. These functions are not listed
-in the Abacus book. They are:
-
-appl_find
-appl_tplay
-appl_trecord
-
-Are they missing from the Atari implementation?
-
-Denny
     They are present in the Atari implementation. There are bugs in
appl_find (see the gem bug list that a posted a few days ago), where
appl_find will find an application even if the application goes away, until
another application is loaded. If you caught Mark Skapnniker's (sp?) article
in the new STarT, he comments that appl_t* functions are very inefficient.
Did you notice that the Balma and fitler book are missing all the vdi input
and vext_* functions. I wonder why? Anyway, when in doubt never trust those
brain damaged Abacus books!!

Hello,
  My name is Paul Jeran, I purchased an Atari 520ST is August of this year
right now I am having trouble with the keyboard. Sometimes the keys won't
respond unless a VERY firm tap is used. It only occurs in certian keys,

'T','Q','E' and CTRL. I use the computer every day as a terminal and word processor. If anyone can offer sugestions I would be thankful. Is there any way Atari could send me a replacement keyboard and I will send the on I have back (It is still under the 90 days).

Thank You,
Paul Jeran

I would appreciate the Net's opinion on the following:

If I want to do serious word processing and be able to embed graphics (e.g. illustrations) and equations (with few limitations), do multi-column layouts (e.g. for persnickety journals) and move all of the above around freely to re-arrange the page, what software would be the best choice to do all of the above on an ST?

In particular, does anybody know if the MacIntosh software that does such things is among the packages that one can run on an ST with Magic Sac?

How much memory would be necessary to make it all practical?

Does anyone know if there is an ST package that produces PostScript (page description language) output that can run real typesetters as well as some laser printers?

In short, should I buy a Mac or an ST?

Thanks for any help that is forthcoming!!!

I just received BI's THUNDER version 1.3 Spelling checker and I am impressed!
It is both an online checker, meaning it checks words as you type, or it will
check an entire document. It also can do statistics on the piece and tell you
what grade level your writing is on.

Version 1.3 corrects some problems with the older versions. It also includes
an Anagram function which can incredibly solve anagrams at lightning speed.

I bought THUNDER through Software Discounters of America (1-800-225-7638).
They get my four star **** recomendation. They have a toll free number,
accept credit cards, have low prices, and super fast UPS delivery.

The views expressed are my own and do not reflect those of my company....

To Bill Pase and all interested:

>For your floppy format program. You suggest running it from an auto
>folder. Should this be when booting with an RAM TOS? And if so is it
>then like the Analog one wherein you then reboot after formating as many
>disks as you wish? /bill

First of all, as much as I would like to, I cannot take credit for frmtplus:
I got this from the Atari BBS (there is some nice stuff out there). Now,
you are correct about placing the program in the AUTO folder of your RAM TOS
boot disk (i.e., you _must_ boot with TOS in RAM for the program to work).
Once the desktop appears, you may then format as many disks as you wish (I
recommend you format all of your disks this way - even those of you using the
10 sector, 410k/820k formats - since the gain in speed is so nice). Once
you have formatted all the disks you are going to, you may (but don't have
to) boot your machine from ROM.

-Rich

Keywords: If you want it...

    I have discovered the problem people have been having with my
public domain editor TVX. (The problem is with all versions:
TVX, the Vi emulator, and the Emacs emulator.) I would really call
it a bug in GEMDOS, but it shows up in the editor. It only happens
if you have your key repeat rate set too high and hold the up/down
keys down too long. GEMDOS loses track of input/output and dies.
For those of you with source, the solution is to add code to check
for un-read keystrokes in the command interpreter loop in tvx_edit.c.
Just throw away the extra keystrokes inside the loop. This will
make sure that TVX is finished executing one command before the
keyboard overflows. It will also force the screen to match your
keystrokes. It is a bit of a kludge, but works. I will include
the change on any sources I send out from now on (send me 720K
worth of pre-formatted disks and return postage, and I will return
full sources, compiled code, and documentation).

    If there is enough interest (by e-mail reply), I will post
the uuencoded executable of the Vi emulator to this group (plus
a short document). Otherwise, I'll continue my policy

of returning disks with the sources.

    P.S. - I was unable to duplicate the problem of not writing the backup file - I suspect the user just didn't find the right work file.

     Friday afternoon I received V2.0 of the Magic Sac software which had been posted by Federal Express next day service on Thursday. I took it home and tried it out briefly over the weekend.

     There is now a copyaa program which allows people with only one disk drive to make backup copies of their Magic disks.

     The single disk drive copy bug has been fixed.

     FreeTerm now works.

     Also, the problem I was having with the transmit program appears to be fixed, although I didn't have a Mac to check it out with.

     Version 2 comes with a readme which gives a brief list of programs that run under Magic Sac and a more detailed explanation of the problems that might come up when running a program under Magic Sac.

It ain't perfect yet, but I am sure impressed with the service. Four bugs fixed in two weeks, and Federal Express shipping.

Magic Sac is now in a state where I would certainly recommend it as an add on for ST users. You won't be getting a full MacIntosh, but it runs enough Mac software (faster than a Mac) to be worth the price.

Marty

Lines: 38
Keywords: The real story

My previous posting was correct about the cause of the TVX bug, but wrong in the fix. Since this seems to be a general bug/feature of GEMDOS, my solution might be of general interest.

There is some incorrect interaction between GEMDOS function 7 (unechoed keyboard input, probably the others too) and GEMDOS function 9 (print a line, probably the other character at a time, too.).

You can write characters faster to GEMDOS 9 than it can display them on the screen. If you are doing this while the user has the key clamped down at a very fast repeat rate, soon everything will die. The bug seems to be that GEMDOS 9 doesn't bother to check the conout status to see that it can take more characters.

My solution was to go to the bios directly (trap 13), passing up the GEMDOS functions. Character output should be done like this:

```
 char_out(output_char) char output_char;
  {
    while (!bios(8,2))      /* check output status */
     if (bios(1,2))         /* check if input waiting */
         save_input_char(bios(2,2)); /* do SOMETHING with input chr */
    bios(3,2,output_char);  /* now safe to write char */
```

```
  }
```

Apparently, GEMDOS 9 doesn't do the output status check. Maybe
the other GEMDOS character output routines do, but I didn't check
them. (For anyone interested, the REAL fix to TVX is to change
ttwtln to use ttwt, and put the above fix into dispch, and throw
away the extra input characters.)

>To say that Compaq has "released" an 80386 based computer is stretching
>things a bit too, don't you think. They announced it, but said it would
>be available after January. This is similar to what Motorola announced.

Hmmm. According to my brother (a tech at microsoft), Microsoft just installed over 40 of the Compaq 386 machines. His comments:

1. Makes an AT look sick.

2. Extremely fast MS-DOS.

>By the way, IBM is said to be readying an announcment in January for
>their 80386 based machine, which will be available in June. And don't
>forget that a multitasking operating system won't be available until
>around June either. Until then, these 80386 machines are just big
>fast PC's. Meanwhile, Apple is readying a 68020 based machine for
>release early next year.

I have heard (from SCO) that SCO will be releasing Xenix 386 soon. They may already have it running internally. When last I spoke to them they mentioned that Xenix 286 research was being held back in favor of the 386 based machine. An example, they informed me they would never release a large model kernel for the 286.

>Isn't vaporware fun!

Yes, but in this case a multi-tasking OS will probably come available sooner than most people think. Porting anything written for the 286 is a piece of cake.

After many, many problems with BITNET, IBM machines and uudecode, I have found the true answer to having all of my files uudecode. Every single file which has bombed in the past, now decodes perfectly.

The normal sequence that I do is to send the file over from the IBM machine (actually we have an AS/9000N) to the AT&T 3B20 and uudecode on the 3B20. Previously, the only two files which worked were UNITERM and uEmacs.

Now, however, I have found the solution, but I am uncertain as to the exact cause. Here is what I do. First, while in Xedit, I set the logical record length to 61, then I set the record format to fixed. The following commands do this:

set lrecl 61
set recfm f

now, when I send the file to the 3B20, I enter the command:

sf file uue to acs19 at uhnix1

to receive on the 3B20, I enter the command:

receive $job/pnch6 >file.uue

(since the 3B20 is hooked up as a punch machine (yuck). What you do may be different, but I know setting the logical record length and the record format have made all of my files work.)
When I get to the 3B20, I do have to fix the file a little bit. I go to the last line and delete the blanks to end of line, after 'end'. Then I go up one line and make sure that there is only 1 (one) blank on the second to the last line. Then I save the file and uudecode it. All the files I have tried thus far have worked, and most of these have always bombed.

Mike

Last xmas a midi/graphics demo was posted on Compuserve which sounds like
it might fit your needs. I'm not sure what the name was, but I think it was
alite.prg. There were also 6 or 7 xmas songs and pictures posted to go with
the demo (available as 1alite.sng/1alite.pic, 2alite.sng/2alite.pic, etc.).
You should be able to rename any .sng file nalite.sng (where "n" is a number
from 1 to 9) along with a corresponding nalite.pic and have alite.prg play
it back for you through your synth. Does this make sense?   Anyway, if
you like, I'll post my copy along with a couple of .sng/.pic files to
get you started.

There have been several requests for Proff lately, so what the heck.

X * ltb.c - Lexical Table Builder
X *
X * Functional description:
X *
X *  This program builds a file containing the data
X *  structures of a compile-time-initialised hash table.
X *  This hash table may later be used for lexical analysis,
X *  where number of symbols to look up is sufficiently large
X *  to avoid a run-time table initialization.
X *  In order to guarantee the success of this setup, the
X *  hash routine, the lookup and install routines should be
X *  the same between ltb and the lexical analysis.
X *
X * synopsis:
X *
X *  ltb <input file> [table name]
X *
X * input file format:
```

```
X *
X *  <token>  <value identifier> [flag value]
X *
X *  token:        string of alphanumeric characters to be
X *                matched by the lexical analyser (no blanks).
X *           these token strings are "installed" to a hash
X *           table by ltb to avoid run-time overhead.
X *  value
X *  identifier:   A constant name to be used internally by the
X *           lexical analyser in place of the actual
X *           token value. a "#define <indentifier> <value>"
X *           is generated for each value identifier, where
X *           value is an odd and unique integer constant. If
X *           the value identifier is a `*' (star), then the
X *           previous value is repeated. Thus:
X *
X *                 token   ident.   flag
X *
X *                sp   SP   1
X *                space    *        { inherits SP  }
X *                blank    *        { inherits SP  }
X *                .    .    .
X *                .    .    .
X *
X *  flag value:   An additional integer field to pass flags etc. to
X *           the lexical analyser. If not specified, set to
X *           0. token value field must be present for this field
X *           to be obtained.
X *
X * outputs:
X *
X *  ltb generates two C include files:
X *
X *      [tablename].d:  compile time lexical constants (defines)
X *      [tablename].h:     initialised hash table.
X *
X *  where [tablename] is the name of the hash table as specified
X *  in the command line of ltb. If not specified, "lextab" is used
X *  as a default.
X *
X * routines used by LTB:
X *
X *  hash, lookup and a modified version of install routines,
X *  as defined in K&R, pp. 134 - 136.
X *
X * Application areas:
X *
X *  Lexical analysers for compilers, interpreters, spelling
X *  checkers.

X.sect 0 1.0 Introduction
X This manual describes PROFF, a formatter based on the FORMAT utility
Xpresented in
X.ul
XSoftware Tools.
X PROFF was produced to provide a powerful formatter that can be used under
Xa variety of microcomputers, thus providing a consistent formatting tool
Xacross environments. PROFF can be used to format memos, reports, form letters
Xand
Xdocuments such as this manual. It can also be configured to mimic
Xother formatting
Xsystems of similar nature.
X This document itself was produced with PROFF, using most of its advanced
features.
XPROFF took care of such things as auto-paragraphing and the production of
Xthe Table of Contents as the manual was being formatted.
X PROFF was developed under a Digital Equipment Corporation Rainbow 100,
Xusing Mark Williams C Compiler for portability reasons. PROFF is
Xavailable under VAX/VMS operating system. PROFF implementations for
XIBM PC and APPLE ][ microcomputers are also underway.
X.st -14
XRainbow, VAX/VMS are trademarks of Digital Equipment Corporation.
X.br
XMark Williams C Compiler is a trademark of Mark Williams Company.
X.br
XIBM is a registered trademark of International Business Machines Inc.
X.br
XAPPLE is a trademark of Apple Computer Inc.
X.br
XUNIX is a trademark of Bell Laboratories.
X.bp
X.cl
X.sect 0 2.0 General Description
X.cl
X.sect 1 2.1 The Input
X The text that is to be formatted by PROFF is typed into an input file
Xusing any text editor. This file contains the text to be formatted
```

```
Xas well as PROFF commands.
X Each line in the input file is either a command line or a text line. A
Xcommand line is a line that begins with a period (".").  All other lines are
Xtext lines. The command lines are not printed - they tell PROFF how you want
Xit to format the text that follows. Appendix A summarizes all of the PROFF
Xcommands for a quick reference.
X.sect 2 2.1.1 Text
X Text can be entered into the input file in any format. PROFF removes all extra
Xblanks and tabs between words when operating in fill mode. This means you do
Xnot have to worry about how many words you put on a line, and you can break
Xlines wherever it is convenient to your typing. Note however, that you cannot
Xbreak a word between two lines.
X Blanks and tabs at the beginning of a line are not removed. This is useful
Xfor producing special tables and performing special types of indentation.
XThus, normal text lines should not have any leading tabs or blanks.
X.sect 2 2.1.2 Commands
X A command is a line that starts with a period. Immediately following the
Xperiod is a command name. Some commands accept a numeric quantity or a
Xcharacter string parameter, which must be separated from the command name
Xby a space or a comma. For example, an indent command might appear as follows:
X.save
X.in +5
X.nf
X.nj
X.sp
X|
X|It is to do nothing that the elect exists.
X|.in 5
X|- Oscar Wilde
X|
X.restore
X Assuming that the left margin was at column 1, PROFF would produce the
Xfollowing:
X.save
X.in +5
X.nf
X.nj
X.sp
X.need 4
X|
X|It is to do nothing that the elect exists.
X|     - Oscar Wilde
X|
X.restore
X.sp
X(In the examples above, as in those following, the vertical line indicates
Xthe left edge of input or the left edge of the printed page).
X The number following the command may be preceeded by a "+" or "-" sign.
XThis plus or minus sign indicates an addition or subtraction of the number
Xto or from the current value for the command. for example, the text:
X.sp
X.save
X.in +5
```

```
X.nf
X.nj
X.need 11
X|
X|Nothing to do but work,
X|.in +3
X|Nothing to eat but food,
X|.in -3
X|Nothing to wear but clothes
X|.in +3
X|To keep one from going nude.
X|.in +7
X|-Benjamin King
X|
X.in -5
X.sp
Xwill produce as output:
X.sp
X.in +5
X.need 6
X|
X|Nothing to do but work,
X|   Nothing to eat but food,
X|Nothing to wear but clothes
X|   To keep one from going nude.
X|          -Benjamin King
X|
X.restore
X If a number is not supplied with a command that requires a number, PROFF
Xwill use a default value. The defaults for each command are summarized in
XAppendix A.
X.cl
X.sect 1 2.2 The Output
X The main functions performed by PROFF are
X.ul
Xfilling
Xand
X.ul
Xjustifying.
XA line is
Xfilled by packing as many words onto it as will fit. The line is justified
Xby spacing words evenly between the left and right margins. When PROFF starts,
Xit assumes that the text is to be filled and justified. Of course, when fill
Xand justify are not needed (as in the case of a letter or a table), there are
Xcommands to turn these features off, and back on again, as necessary.
X When PROFF is in fill mode, it normally strips out extra spaces and tabs
Xbetween words.
X Many PROFF commands cause a
X.ul
Xbreak
Xto occur in the output. This means that the line currently being filled is
Ximmediately output. Any following text goes into a new output line.
X.cl
```

```
X.sect 1 2.3 Executing PROFF
X Once a text file is ready for formatting, PROFF is started by typing
Xthe program name, various options, name of the input file and the name
Xof the output file. For example the command
X.sp
X.in +5
XA> proff  -po5 proffman.prf proff.man
X.sp
X.in -5
Xwould produce this document as proff.man, from an input file proffman.prf,
Xshifted right by 5 spaces.
X(The symbol "A>" is CP/M system prompt).
X.cl
X.sect 1 2.4 Bibliographic Notes
X  PROFF wa produced by re-writing the Software Tools Formatter FORMAT.
XSome of the ideas are from Freshwater Institute RUNOFF, NROFF,
XUniversity of Waterloo SCRIPT
Xand other formatters of similar nature. The underlying ideas of the
Xmentioned above formatters may be found in
X.ul
XSoftware Tools
Xby B.W. Kernighan and P.J. Plauger. 1976. (Addison-Wesley, Reading, Mass.).

X.sect 0 3.0 Command Descriptions
X This section describes PROFF commands. Commands specify how the program is
Xto process the text lines in the input file. Lines in the input file that
Xbegin with a period (or the control character selected by the user)
Ximmediately followed by a command name are commands. Any line that begins
```

```
Xwith a period and followed by a _# or _! is a comment line and is ignored
Xby PROFF - this allows you to put information in the file that will be neither
Xprocessed nor output by PROFF.
X As described earlier, some of the commands can be followed by "parameters".
XParameters are used in executing a command; for example, in the command
X".sp 3", the parameter "3" tells the formatter to insert 3 blank lines into
Xthe document. The following conventions are used in describing the parameters:
X.sp
X.in +5
X.ti -2
Xo Parameters surrounded by square brackets are optional. If not supplied, PROFF
Xassumes a default value.
X.br
X(e.g. .sp [n])
X.sp
X.ti -2
Xo Parameters surrounded by angle brackets are mandatory. PROFF will display
Xa fatal error message if the parameter is absent. (e.g. .set <variable name>)
X.sp
X.ti -2
Xo Parameters surrounded by squiggly brackets are to be typed exactly as
Xindicated. (e.g. .pn {roman})
X.sp
X.ti -2
Xo A bar character seperating the parameters within brackets indicate an
Xalternative. (e.g. .st [+|-][n] means both .st [+n] and .st [-n])
X.in -5
X In describing the commands, the command is typed exacty as accepted by PROFF
Xwith the associated control character default ("."). If more than one form of
Xthe command is accepted by PROFF, the command names are separated with a
Xbar indicating an alternative.
X.bp
X.cl

X.!
```

```
X.cchar \
X\!
X\! Variable creation
X\! We use variables to avoid re-typing of multiple options over
X\! and over again. These variable names will be reused in the
X\! appendix to produce a quick referance
X\!
X\set FILL ".fi | .f | .fill"
X\comm FILL
XThe fill command causes a line to be filled with as many words as the right
Xmargin allows. For this purpose, all extra blanks and tabs are removed between
Xwords. Each word is separated with a single blank. PROFF automatically assumes
Xfill mode during the startup.
X\set NOFILL ".nf | .nofill"
X\comm NOFILL
XNo fill discontinues the filling of the text. PROFF simply copies the text
Xto the output. This command may be used to pass tables and other text
Xunaltered through the formatter.
X\set JUST ".ju | .j | .justify"
X\comm JUST
XJustify causes the words on a line to be evenly spaced between the left and
Xthe right margins. Note that lines can be justified only if lines are also
Xbeing filled. PROFF automatically assumes justify mode during the startup.
X\set NOJUST ".nj | .nojustify"
X\comm NOJUST
XNo justify discontinues the text justification.
X\in -5
X\cchar .
X.bp
X.cl
X.sect 1 3.2 Text Formatting
X.in +5
X.cchar \
X\set BREAK ".br | .break"
X\comm BREAK
XBreak causes a break: the current line is printed without justification,
Xand the next word is placed at the beginning of a new line. Note that many
XPROFF commands cause an implicit break.
X\set INDENT ".in | .lm | .leftmargin [+|-][n]"
X\comm INDENT
XIndent causes a break and indents the following lines [n] spaces to the
Xright of the left margin. [n] can be negative to allow beginning a line
Xto the left of the left margin, however, a line cannot begin to the left of
Xcolumn 0. If a plus or minus sign is used with n, then [n] is added or
Xsubtracted to or from the current value.
X\set TINDENT ".ti | .i | .left [+|-][n]"
X\comm TINDENT
XTemporary indent is identical to the indent command except that it
Xapplies only to the next line of printed text. Thus, the command
X".ti +5" would cause the next line to be printed 5 spaces to the right
Xof those that follow.
X\set SPACETO ".st | .spaceto [-][n]"
X\comm SPACETO
```

```
XSpaceto allows spacing to line [n] from the top of the current page.
XIf a negative [n] is specified, than spacing is performed to line [n]
Xfrom the bottom of the page (excluding the footer lines). Thus, footnotes
Xcan be set at a fixed distance from the bottom of the page by a command such
Xas ".st -5".
X\set SPACE ".sp | .s | .skip [n]"
X\comm SPACE
XSpace causes a break and skips [n] lines, except at the top of
Xa page. The space command
Xis dependent on the setting of line spacing.
X\set CENTER ".ce | .center [n | on | off]"
X\comm CENTER
XCenter causes the next [n] lines of text to be centered between the left
Xand right margins. Centering may be started with "on" and terminated with
X"off", in which case all input lines between these commands will be centered.
X\set UNDLINE ".ul | .underline [n | on | off]"
X\comm UNDLINE
XUnderline command causes the text on the next [n] input lines to be underlined
Xwhen printed. If [n] is omitted, only the next line is underlined. This command
Xdoes not cause a break, so words in filled text may be underlined by:
X\sp
X\save
X\cchar .
X.in +5
X.nf
X.need 11
X.sp
X|
X|The "Pay-off" Theory: Only
X|.ul
X|losers
X|believe in luck, horses, horoscopes
X|and
X|.ul
X|lotteries.
X|

Xlosers
Xbelieve in
X.br
X|luck, horses, horoscopes and
X.ul
Xlotteries.
X.br
```

```
X|
X.sp
X.restore
XUnderlining may be started with "on" and terminated with "off", similar to
Xthe centering command.
X\set CUNDLINE ".ul | .underline [all | words]"
X\comm CUNDLINE
XThis version of the underline command is used to set the mode of
Xunderlining:
X\sp
X\nap
X\in +5
X\nf
Xall   - underline across all characters,
X        including spaces.
X\br
Xwords - underline words only
X\fi
X\sp
X\in -5
X\ap
X\set BOLD ".bd | .bold [n | on | off]"
X\comm BOLD
XThe bold command causes the text on the next [n] input lines to be highlighted
Xby overstriking. If [n] is omitted, only the next line is highlighted.
XBolding may be started with "on" and terminated with "off" as in the
Xcase of the center and underline commands.
X\set DBO ".db | .dbo | .disablebolding"
X\comm DBO
XTurns the bolding off, all bolding commands are ignored. This feature is
Xuseful for rough drafts.
X\set EBO ".eb | .ebo | .enablebolding"
X\comm EBO
XTurns the bolding feature back on. Bolding is turned on during the PROFF
Xstartup.
X\in -5
X\cchar .
X.bp
X.cl
X.sect 1 3.3 Page Formatting
X.in +5
X.cchar \
X\set LS ".ls | .spc | .spacing [n]"
X\comm LS
XLine spacing is the command to set line spacing. Set n to 1 for single spacing,
X2 for double spacing etc.
X\set BP ".bp | .pg | .page [n]"
X\comm BP
XThe begin page command causes a break, ends the current page, outputs
Xfooters if required and begins a new page. If [n] is present, the page number
Xis set to [n]. The default action is to number the pages incrementally.
X\set PN ".pn | .pagenumber {roman} | {arabic}"
X\comm PN
```

```
XPage number command defines the format of the page number. Uppercase roman
Xnumerals may be obtained with "roman" keyword. To convert the page numbers
Xback to normal, "arabic" is specified. PROFF uses arabic numerals as
Xa default.
X\set NPA ".np | .nopaging"
X\comm NPA
XNo paging disables the pagination. When PROFF is in no paging mode,
X"begin page" (.bp) and "page length" (.pl) commands are ignored. This mode
Xof operation is especially useful for using the proff output with the
Xmulti-column formatter (MC).
X\set PA ".pa | .paging"
X\comm PA
XPaging enables normal page generation. This command starts a
Xnew page and restores the page length to the
Xvalue previous to the ".np" command.
X\set NE ".ne | .need | .tp | .testpage [n]"
X\comm NE
XTest page checks to see whether at least [n] lines remain in the
Xcurrent page. If less than this number of lines remain, printing will resume
Xat the top of a new page. If [n] is missing, it is assumed to be zero.
X\set HE ".he | .header <text>"
X\comm HE
XHeader sets the text to be printed on top of each page. <text> is
Xdivided into sections which are to be left justified, centered and right
Xjustified. To divide <text> into these three parts, the first character is
Xassumed to be a separator. (e.g. /left/center/right/) But any non-alphanumeric
Xcharacter may also be used. The characters "#" and "%" are replaced with the
Xcurrent page number and day/time in the header.
X\set FO ".fo | .footer <text>"
X\comm FO
XFooter is identical to header except that it sets the text to be printed
Xat the bottom of each page.
X\set OHE ".oh <text>"
X\comm OHE
XThe odd header command sets the header for odd pages only.
X\set EHE ".eh <text>"
X\comm EHE
XThe even header command sets the header for even pages only.
X\set OFO ".of <text>"
X\comm OFO
XThe odd footer command sets the footer for odd pages only.

X    |                           |
X.fi
X.in +5
X.cchar \
X\set PO ".po | .offset [+|-][n]"
X\comm PO
XThe page offset command moves the entire page to the right or left depending on
the
Xspecified value. All indentation is according to the page offset. PROFF
Xassumes a page offset of 0 during the startup. If [n] is specified with a
Xplus or minus, it will be added or subtracted from the current value.
X\set RM ".rm | .rightmargin [+|-][n]"
X\comm RM
XRight Margin sets the position of the last printable character from the
Xleft edge of the page to [n]. Default value for right margin is 65.
XA plus or minus value will be added or subtracted from the current value.
XIf [n] is not specified, right margin is set to the default value.
X\set PL ".pl | .ps | .pagesize [n]"
X\comm PL
XPage length is used to set the number of lines that are to be printed
Xon a page including the header and footer lines. After [n] lines are printed,
Xthe paper will advance to the top of next page. The default page length is
X66 lines (11 inches for 6 lines/inch). This command is disabled if nopaging
Xis set.
```

```
X\set M1 ".m1 [n]"
X\comm M1
XMargin 1 sets the number of lines (including the header) which will be left at
Xthe top of the page to [n]. The default setting is 3. If [n] is omitted, is
Xset to the default.
X\set M2 ".m2 [n]"
X\comm M2
XMargin 2 sets the number of blank lines between the header and the first
Xline of text. The default setting is 2.
X\set M3 ".m3 [n]"
X\comm M3
XMargin 3 sets the number of blank lines between the footer and the last line
Xof text. The default setting is 2.
X\set M4 ".m4 [n]"
X\comm M4
XMargin 4 sets the number of lines (including the footer) which will be left at
Xthe bottom of the page to [n]. The default setting is 3.

X.sect 1 3.5 Table of Contents
X This section describes the the commands that are used to generate a table of
Xcontents. Basically, a contents line command is used in every place in
Xthe document where an entry is needed in the table of contents. PROFF
Xstores the text and the page number when it encounters this command.
XAfter the the body of the document is processed, a print contents command
Xdumps the contents table. The contents should be dumped in a new page, with
Xnofill. Page numbering should be disabled if the table of contents is to be
Xused in front of the document.
X.sp
X.in +5
X.ap
X.cchar \
X\set CL ".cl | .contline [<n> <text>]"
X\comm CL
XContents line specifies a line of <text> to be entered into the table of
Xcontents. <n> specifies the level at which the item is to be printed
Xin the table. When the table is printed, each level of entry will be
Xindented by specific number of spaces.
X<text> appears in the output exactly as it appears
Xin the contents line command, except that leading blanks are removed.
XIf no options specified in the contents line, a blank is inserted during
Xthe table output.
X\set PC ".pc | .printcont [n]"
X\comm PC
XPrint Contents causes the currently accumulated table of contents to be
Xprinted. If [n] is specified, it is used as the indent value for each
Xlevel.  If [n] is not specified, it is defaulted to 3.
X A contents line at level 0 is as wide as rightmargin-indent. The
Xoutlook of the table of contents may be changed by altering the right
Xmargin and indent values. A typical table of contents may be produced as
```

```
Xfollows:

X.sect 1 3.6 Miscellaneous
X This section describes miscellaneous commands that radically increase the
Xformatting powers of PROFF. With the assistance of variables, PROFF can
Xgenerate form letters and documents with dynamic parts. The ability to save
Xand restore formatter context eliminates the need to remember the exact
Xsettings of the formatter across the document.
X.in +5
X.cchar \
X\set VSET ".vs | .set <variable> [definition]"
X\comm VSET
XSet variable  defines a variable to be later used in the document.
XIf the definition part is left out, PROFF uses the variable name as a prompt
Xand allows the user to define the variable interactively. Variable names cannot
Xstart with a numeric character, and may only contain alphanumeric
Xcharacters. The definition of a variable may not contain any blanks, unless
Xthey are surrounded by double-quotes. To get a double quote within a a quoted
Xdefinition, two double-quotes are used.
X Once the variable is
Xdefined, it can be used anywhere in the document, including the command
Xline itself. A variable substitution is invoked by a dollar sign (_$). (A
Xliteral _$ is inserted into text using ___$).
XA variable name must be delimited by a non-alphanumeric character within the
Xtext. If the contents of the variable is to be appended to other
Xalphanumeric characters, it must be surrounded by wiggly braces
X("{" and "}"). The following is an example of variable usage:
X\need 12
```

```
X\sp
X\nf
X|.nf
X|.vs v1 Murphy
X|_${v1}'s first law:
X|   Nothing is as easy as it looks.
X|_${v1}'s second law:
X|   Everything takes longer than you think.
X|Charley's observation:
X|   Computers were invented by _$v1.
X|
X\sp
XProduces the following:
X\sp
X\need 8
X|
X|Murphy's first law:
X|   Nothing is as easy as it looks.
X|Murphy's second law:
X|   Everything takes longer than you think.
X|Charley's observation:
X|   Computers were invented by Murphy.
X|
X\sp
X\fi
X\set VGET ".vg | .get <variable> <prompt>"
X\comm VGET
XGet variable is the interactive version of variable definition. In this
Xvariant, a prompt string is used to obtain the value of the variable,
Xwhich is typed at the user's terminal. If the prompt string is to
Xcontain blanks, tabs etc., it must be enclosed in double quotes. No quotes
Xare necessary for input text.
X\set VRG ".nr <a-z> [+|-][n]"
X\comm VRG
XNumber register is used to define registers that contain numeric values.
XThere are 26 number registers, named a-z. The command ".nr x n" sets the
Xnumber register "x" to value n; ".nr x +n" increments the number register
Xby n; ".nr x -n" decrements the number register by n. The value of the
Xnumber register x is placed in the text by the appearance of _@nx. A literal
X_@ may be inserted using ___@.
XNumber registers may be used on command lines and anywhere in the text.
X\set CCHAR ".cc | .cchar [char]"
X\comm CCHAR
XControl Character  sets the character that distinguishes PROFF
Xcommands from text to be formatted. As a default, control character is set to
X(".") period.
XThis character may be changed to something other than a period, either
Xto mimic other formatters or to disallow interpretation of lines beginning
Xwith a period. (This document makes heavy use of the .cc command).
X\set ECHAR ".ec | .echar [char]"
X\comm ECHAR
XEscape Character  sets the character that disallows the
Xinterpretation of spacial characters such as _@ and _$. PROFF uses an
```

```
Xunderline ("__") character as a default.
X\set SOU ".so | .source | .include | .require [filename]"
X\comm SOU
XThe source (include) command allows external files to be inserted into the
Xinput file
Xduring the formatting. Using this feature, tables, graphs and other
Xdocuments generated outside PROFF may be included into the document
Xbeing formatted. This feature is also very useful in including a common set
Xof macros during formatting. Include files may be nested inside other
Xinclude files. Currently, PROFF only allows a nested include
Xfiles level of 8. Filename may be enclosed in quotes.
X\set SAVE ".sv | .save"
X\comm SAVE
XThe save command allows the saving of the current formatter context on a
Xpushdown stack. The saved context of the formatter segment (FSECT) includes
Xthe following values and flags:
X\need 14
X\sp
X\nf
X\nap
Xvalues            flags         on   |  off
X------           -----
Xindent       (.in)    fill     (.fi | .nf)
Xright margin (.rm)    justify  (.ju | .nj)
Xoffset       (.po)    paging   (.pa | .np)
Xline spacing (.ls)    number type        (.pn)
Xpage length  (.pl)    bolding       (.eb | .db)
Xmargin values     (.m1)    autoparagraph (.ap | .na)
X         (.m2)
X         (.m3)
X         (.m4)
Xcontrol char (.cc)
Xescape char  (.ec)
X\sp
X\ap
X\fi
X\set RST ".rs | .restore"
X\comm RST
XThe restore command pops the context stack and restores the values and flags
Xas defined above.
X\set LEX ".lx | .lex <command> [equate]"
X\comm LEX
XThe lexical modification command is essentially a permanent replacement of a
Xgiven command. This command is used for changing the command names without
Xresorting to the macro facility. Lex permanently removes the old
Xcommand name from command tables and replaces it with the new definition.
XIf the equate is not specified, the command  becomes undefined and is
Xno longer recognised by PROFF. The command equate should not contain
Xnon-alphanumeric characters.
X\set APR ".ap | .autoparagraph"
X\comm APR
XThe autoparagraph command turns on the automatic paragraphing feature. If
Xauto-paragraphing is on, every line that starts with a
```

```
X\ul
Xblank
Xor a
X\ul
Xtab
Xcharacter starts a new paragraph. A new line is generated (.sp) and
Xthe beginning of the paragraph is indented by five spaces.
XAutoparagraphing is the equivalent of the following commands:
X\in +5
X\nf
X|
X|textextextextext
X|.sp
X|.ti +5
X|textextextextext
X|
X\in -5
X\fi
X\set NAP ".na | nap | .noautoparagraph"
X\comm NAP
XNo Autoparagraph command disables auto-paragraphing.
X\set WRT ".wr | .write <string>"
X\comm WRT
XWrite is a special output command, only to be used to configure printers
Xand other output devices with escape sequences. This command outputs the
Xassociated string as it is encountered, without going through the normal
Xoutput routines of the formatter. Currently, the output string may contain
Xcontrol characters specified as "^<char>", decimal numbers within the range
Xof 1-255, and other characters. Blanks within the string are skipped. Any
Xportion of the string enclosed with double quotes is output as is. To output
Xa double quote, two double quotes must be used within the quoted string.
XFollowing is a typical string to set a Digital La-100 printer to letter
Xquality print mode:
X\sp
X\nf
X\in +5
X|
X|.wr ^["[2z"
X|
X\sp
X\fi
X\in -5
XIn the control string, "^[" is the ASCII equivalent of the Escape (esc)
character.
XFollowing mapping table is used to convert characters starting with a caret
Xto their binary equivalents: ("|" indicates an alternative)
X\nf
X\nap
X\sp
X\in +5
XControl chr  Dec. Oct. Hex.

X.sect 1 3.7 Defining New Commands (Macros)
X In document formatting, it is common to repeat a series of commands at
Xseveral places in the document. PROFF allows you to define a new command
Xthat will replace these repeated commands. This not only saves typing but
Xensures that
X.ul
Xexactly
Xthe same sequence of commands are applied throughout the document. A new
Xcommand that you define is formally called a
X.ul
Xmacro.
XTo define a macro, you must use the define macro (.de | .define) and
Xend macro (.en) commands.
X.in +5
X.cchar \
```

```
X\set DEF ".de | .define <macro name>"
X\comm DEF
XDefine is used to define a <macro name> to which a series of commands to
Xbe assigned. This definition line is followed by any number of PROFF
Xcommands and/or text which define the action that the macro
Xwill subsequently produce. Macros may refer to other macros.
X\set ENM ".en"
X\comm ENM
XEnd macro is the last line in the command definition. You must put in this
Xcommand to finish a currently defined macro. ".en" command should not be
Xre-defined as a macro.
X\in -5
X\sp
XThe example below defines macros ".note" and ".endnote", similar to the
XRUNOFF commands of the same name.
X\in +5
X\nap
X\nf
X\need 20
X\sp
X|
X|.define note
X|.sp
X|.ce
X|NOTE
X|.sp
X|.fi
X|.in +5
X|.rm -5
X|.en
X|
X|.define endnote
X|.sp
X|.nf
X|.in -5
X|.rm +5
X|.en
X|
X\in -5
X\ap
X\fi
X A macro is used like any other PROFF command, control character followed
Ximmediately  by the name of the macro. For example, the above macros
Xmay be used as follows:
X\in +5
X\nap
X\need 9
X\nf
X\sp
X|
X|.note
X|textextextextextextextextextext
X|              .
```

```
X|          .
X|          .
X|.endnote
X|
X\in -5
X\sp
X\fi
XThe following note is generated by the same macros described previously.
X\cc .
X.nap
X.note
XFlap's Law: Any inanimate object, regardless of its position or configuration,
Xmay be expected to perform at any time in a totally unexpected manner for
Xreasons that are either entirely obscure or else completely mysterious.
X.endnote
X.fi
X.cc \
X\ap
XSpecial symbols may be used within a macro definition. These symbols represent
Xthe parameters passed to a macro, delimited by blanks or commas.
XThese symbols are _$0 for macro name, _$1 for the first parameter, _$2 for
Xthe second parameter and so on, up to _$9 for the ninth parameter. Currently,
Xmacro parameters may only contain alphanumerics, no string parameters are
Xpossible. The previous macro "note" may now be defined as follows:
X\in +5
X\nap
X\nf
X\need 20
X\sp
X|
X|.define note
X|.sp
X|.ce
X|_$2 _$3 _$4 _$5 _$6 _$7 _$8 _$9
X|.nr m _$1
X|.sp
X|.fi
X|.in +_$1
X|.rm -_$1
X|.en
X|
X|.define endnote
X|.sp
X|.nf
X|.in -_@nm
X|.rm +_@nm
X|.en
X|
X\in -5
X\ap
X\fi
X In this version of the "note" and "endnote" macros, the first parameter (_$1)
Xis used to pass the value for indentation and right margin adjustment.
```

```
XAll the rest of the macro parameters (_$2 - _$9) are used as the title of
Xthe note. The indent value passed as the first parameter is also saved in the
Xnumber register "m" to communicate it to the "endnote" macro, such that
Xwhen the endnote macro is called, both indent and right margin values are
Xadjusted back to normal. It is possible and may be more useful to use
X".save" and ".restore" commands to accomplish the same task, especially if
Xthe macro alters the current formatting context drastically. The ".note"
Xand ".endnote" macros may be called as follows:
X\in +5
X\nap
X\need 9
X\nf
X\sp
X|
X|.note 5 Asimov's Law of Robotics
X|textextextextextextextextextext
X|              .
X|          .
X|          .
X|.endnote
X|
X\in -5
X\fi
X\ap
X In this usage, the indent value will be adjusted by +5, right margin will
Xbe adjusted by -5, and the title "Asimov's Law of Robotics" will appear
Xcentered above the note.
X\cchar .
X.bp
X.cl
X.sect 0 4.0 Executing PROFF
X The PROFF program  may be invoked with a series of optional parameters and
Xfilenames on the command line. The command synopsis is:
X
XPROFF [+n] [-n] [-v] [-s] [-pon] [-ifile] input [output]
X
XThe square brackets indicate an optional parameter. Interpretation of the
Xparameters is as follows:
X.nap
X.in +10
X.define opt
X.need 5
X.sp
X.ti -5
X.bd
X$1
X.br
X.en
X.opt +n
XStart the printing of the document at the first page with
Xnumber n.
X.opt -n
XStop printing at the first page numbered higher than n.
```

```
X.opt -v
XVerbose mode. PROFF indicates the source files being included into
Xdocument, and produces a summary of the number of textlines read in, the number
Xof lines and actual pages generated. A memory usage summary of internal
Xstorage for macros, stacks and tables is also displayed.
X.opt -s
XStop before each page, including the first one to allow paper
Xadjustment. A prompt is given just before the first page. For each
Xpage thereafter, the terminal bell is rung to indicate that another sheet
Xof paper is needed.
X.opt -pon
XSets the page offset to n. This is equivalent to ".po" command within
Xthe document. It is recommended that -pon option be used instead of
Xembedding the offset value within the document.
X.opt -ifile
XIncludes the given file to the formatted document. This is equivalent to
Xa ".include file" command within the document. This option may be
Xrepeated more than once, -ifile1 -ifile2 etc.
X.opt input
XSpecifies the input file to be formatted. PROFF does not impose any
Xfile extension. The recommended extension is ".PRF".
X.opt output
XSpecifies the output file for the formatted document. If this is omitted,
Xoutput is directed to the user's terminal.
X.in -10
X
XFollowing are some examples of PROFF command lines:
X
X.ti +5
XA>PROFF -v proffman.prf
X
XFormat this document (proffman.prf) in verbose mode, and output the
Xformatted document to the
Xterminal.
X
X.ti +5
XA>PROFF +5 -imacros.pma proffman.prf
X
XFormat this document, include the external file MACROS.PMA, skip the first
Xfour pages and output the formatted document to the terminal.
X
X.ti +5
XA>PROFF -po10 proffman.prf proff.man
X
XFormat this document, shift the entire document by 10 spaces to right and
Xoutput to a file called proff.man.
X.bp
X.cl
X.sect 0 5.0 Tips on using PROFF
X.ap
X.sect 1 5.1 Care and Feeding of Memory
X PROFF uses a dynamic memory allocation scheme for some of its operations.
XThese are macro definitions, contents lines, variables and save context
```

```
Xoperation.
XRunning PROFF under microcomputers with limited memory resources (64k or less)
Xrequire some care in using these commands:
X.list 3
X.item a)
XDo not declare macros that are not needed within the document.
X.item b)
XDo not use comments within macros. Due to delayed evaluation, comments
Xwill also be stored as a part of the macro definition.
X.item c)
XWhere possible, avoid using too much text within macros. It is just as
Xeasy to pass the information during the macro call.
X.item d)
XUse only the shortest form of commands within macros.
X.item e)
XBe brief in contents line text.
X.item f)
XUse short variable names as long as it is not so cryptic as to be confusing.
X.item g)
XAvoid unnecessary blanks within the variable definitions.
X.item h)
XAvoid too many context saves without a corresponding restore. The restore
Xoperation reclaims the memory used for a save.
X.nolist
X Even if the formatter is used with a system of large memory resources,
Xsome of the precautions above are applicable. (Utz's 4th law of Computer
XProgramming: Any given program will eventually expand to fill all the
Xavailable memory.) Using the -v option under memory-restricted systems
Xmay be useful in determining the memory usage.
X
X.sect 1 5.2 Formatting without fuss
X PROFF, using its default settings, may provide reasonably formatted output
Xin many situations.
XAs an example, examine the document PROFF.TUT. This document does not use
XANY formatting commands. All formatting is done with the default settings.
X
X.sect 1 5.3 Variables within macros
X Variable expansions may be performed within the macros. Typically, one
Xof the parameters of the macro is assumed to be a variable, which is expanded
Xonly after the macro is used. Thus:
X.in +5
X.nf
X
X|
X|.define xx
X|.ce
X|_$_$1
X|.cl _$_$1
X|.en
X|
X
X.in -5
X.fi
```

```
XThe macro xx assumes the first parameter to be a variable, which is
Xcentered on the page, and also entered in the table of contents.
XNote the usage of "_$_$1". The lines within a macro are scanned from
Xright to left for parameter expansion. Thus, "_$1" is expanded first,
Xresulting in "_$<first parameter>". This is later expanded as a variable.
X
X.bp
X.cl
X.sect 0 6.0 Example macros
X
X.nf
X.in +5
X.cc \
X.!
X.! macros to create a point-form lists.
X.! note the use of number registers within
X.! the macros.
X.!------------
X.define list
X.nr a _$1
X.in _$1
X.en
X.!------------
X.define item
X.sp
X.ti -_@na
X_$1
X.en
X.!------------
X.define nolist
X.in -_@na
X.sp
X.en
X.!------------
X
X\in -5
X\fi
XThe "list" macro is used to generate point-form lists. The first parameter
Xis an indent value, size of point-str + 1. A typical usage may be as
Xfollows:
X\need 16
X\in +5
X
X\nf
X|
X|Project work involves:
X|.sp
X|.list 3     { size-of-point-str + 1 }
X|.item a)         { "a)" is the point-str }
X|choosing a topic
X|.item b)
X|defining the topic
X|.item c)
```

```
X|research
X|.item d)
X|organizing the notes
X|{etc.}
X|.nolist     { readjusts the indent  }
X|
X\in -5
X
XThe above usage will produce the following:
X\need 12
X\in +5
X
X|
X|Project work involves:
X|
X|a) choosing a topic
X|
X|b) defining the topic
X|
X|c) research
X|
X|d) organizing the notes
X|
X
X\in -5
X\fi
XThe point-form recommendations under section 5.1 (Care and Feeding of
XMemory) were generated with the same set of macros described above.

XSummary of Commands
X
X-----------------------------------------------------------
X$FILL
X        default:  initial: yes  break: yes
```

```
X        begin filling output lines
X-------------------------------------------------------
X$NOFILL
X        default: initial: no   break: yes
X        stop filling
X-------------------------------------------------------
X$JUST
X        default: initial: yes  break: yes
X        begin justifying filled lines
X-------------------------------------------------------
X$NOJUST
X        default: initial: no   break: yes
X        stop justifying
X-------------------------------------------------------
X$BREAK
X        default: initial: break: yes
X        cause a break and output current line
X-------------------------------------------------------
X$INDENT
X        default: 0    inital: 0break: yes
X        set left margin to column n+1
X-------------------------------------------------------
X$TINDENT
X        default: 0    initial: break: yes
X        temporarily indent next output n spaces
X-------------------------------------------------------
X$SPACETO
X        default: 0    initial: break: yes
X        space to line +n from top
X        space to line -n from bottom
X-------------------------------------------------------
X$SPACE
X        default: 1    initial: break: yes
X        space n lines except at top of page
X-------------------------------------------------------
X$CENTER
X        default: 1    initial       break: yes
X        center next n lines
X        center until turned off
X-------------------------------------------------------
X$UNDLINE
X        default: 1    initial       break: no
X        underline next n lines
X        underline until turned off
X-------------------------------------------------------
X\bp
X-------------------------------------------------------
X$CUNDLINE
X        default: words     initial: words     break: no
X        set mode for underline - words or all
X-------------------------------------------------------
X$BOLD
X        default: 1    initial: break: no
```

```
X        boldface (overstrike) next n lines
X        boldface until turned off
X-------------------------------------------------------
X$DBO
X        default: initial: no   break: no
X        disable bolding
X-------------------------------------------------------
X$EBO
X        default: initial: yes  break: no
X        enable bolding
X-------------------------------------------------------
X$LS
X        default: 1    initial: 1    break: no
X        set line spacing to n
X-------------------------------------------------------
X$BP
X        default: +1   initial: 1    break: yes
X        begin a new page and number it n
X-------------------------------------------------------
X$PN
X        default: initial: arabic    break: no
X        set page numbering to arabic or roman
X-------------------------------------------------------
X$NPA
X        default: initial: no   break: yes
X        disable paging
X-------------------------------------------------------
X$PA
X        default: initial: yes  break: yes
X        enable paging
X-------------------------------------------------------
X$NE
X        default: 0    initial: break: yes/no
X        need n lines. Break and generate a new page
X        if not available
X-------------------------------------------------------
X$HE
X        default: null initial: null break: no
X        set header to text (/left/center/right/)
X-------------------------------------------------------
X$FO
X        default: null initial: null break: no
X        set footer to text (/lef/center/right/)
X-------------------------------------------------------
X\bp
X-------------------------------------------------------
X$OHE
X        default: null initial: null break: no
X        set header on odd pages to text
X-------------------------------------------------------
X$EHE
X        default: null initial: null break: no
X        set header on even pages to text
```

```
X-----------------------------------------------------------
X$OFO
X        default: null initial: null break: no
X        set footer on odd pages to text
X-----------------------------------------------------------
X$EFO
X        default: null initial: null break: no
X        set footer on odd pages to text
X-----------------------------------------------------------
X$PO
X        default: 0    initial: 0    break: yes
X        set page offset to n spaces
X-----------------------------------------------------------
X$RM
X        default: 65   initial: 65   break: no
X        set right margin to column n
X-----------------------------------------------------------
X$PL
X        default: 66   initial: 66   break: no
X        set page length to n lines
X-----------------------------------------------------------
X$M1
X        default: 3    initial: 3    break: no
X        lines between top of page and header
X-----------------------------------------------------------
X$M2
X        default: 2    initial: 2    break: no
X        lines between header and text
X-----------------------------------------------------------
X$M3
X        default: 2    initial: 2    break: no
X        lines between text and footer
X-----------------------------------------------------------
X$M4
X        default: 3    initial: 3    break: no
X        lines between footer and bottom
X-----------------------------------------------------------
X$CL
X        default: initial: break: yes
X        enter text into table of contents at level
X        n
X-----------------------------------------------------------
X\bp
X-----------------------------------------------------------
X$PC
X        default: 3    initial: 3    break: yes
X        print table of contents, indent each level
X        n spaces
X-----------------------------------------------------------
X$VSET
X        default: initial: break: no
X        set variable to text
X-----------------------------------------------------------
```

```
X$VGET
X        default: initial: break: no
X        set variable interactively, using text
X        as prompt
X-------------------------------------------------------
X$VRG
X        default: 0    initial: 0    break: no
X        set number register (a-z) to n
X-------------------------------------------------------
X$CCHAR
X        default: "."  initial: "."  break: no
X        set command control character to char
X-------------------------------------------------------
X$ECHAR
X        default: "__" initial: "__" break: no
X        set universal escape character to char
X-------------------------------------------------------
X$SOU
X        default: initial: input    break: no
X        switch input to file
X-------------------------------------------------------
X$SAVE
X        default: initial: break: yes
X        save the current formatter context on
X        context stack
X-------------------------------------------------------
X$RST
X        default: initial: break: yes
X        restore the formatter context from context
X        stack
X-------------------------------------------------------
X$LEX
X        default: initial: break: no
X        rename a command
X-------------------------------------------------------
X$APR
X        default: initial: no   break: no
X        enable auto-paragraphing
X-------------------------------------------------------
X\bp
X-------------------------------------------------------
X$NAP
X        default: initial: yes  break: no
X        disable auto-paragraphing
X-------------------------------------------------------
X$WRT
X        default: initial: break: no
X        write a special string to output. line
X        counter does not change
X-------------------------------------------------------
X$DEF
X        default: initial: break: no
X        define a macro command - ends at ".en"
```

```
X-----------------------------------------------------------
X$ENM
X        default: initial: break: no
X        end the macro definition
X-----------------------------------------------------------

XProff - A portable formatter
X
XThis is the first distribution of PROFF, a formatter based
Xon software tools ROFF. It is mainly a C re-write of ROFF,
X(now known as FORMAT), with some expansions. It is mainly
Xintended for non-UN*X systems, CP/M, MS-DOS and the like.
X
XProff was originally written for The Faculty of Administrative
XStudies, York University, tto supplement their microcomputer
Xenvironment. As of this release, the formatter is in the
Xcontrol of The Faculty of Administrative Studies.
X
XThere is no man page for proff, for it was never intended
Xfor UN*X systems. There is, however two comprehensive
Xdocuments to answer all questions.
X
XThe C code for PROFF is quite warped, and should be approached
Xcarefully. [Ok..Ok.. it is all my fault.. too much midnight
Xoil..]  It is reasonably customazible, by changing proffsym.new.
XThis file is processed by ltb, a static hash table generator.
```

```
XThis approach is most useful to change the operator keywords,
Xcreate aliases, and it also bypassess the initialization
Xoverhead. [see the makefile for the right output file names
Xfor ltb]
X
XPROFF is not copyrighted, at least for this release. Future
Xreleases may contain York University copyright.
X
XPlease send me all updates, bugfixes and other tidbits,
Xso that future releases may be coordinated smoothly.
X
Xenjoy.

X    After capturing and unshar'ing all the parts of this proff
Xposting you should end up with the following files:
X
Xproff.uud             lookup.h  proff.c       putwrd.c
Xdebug.h      lextab.d  ltb.c         proff.h       pxlex.c
Xdecl.h       lextab.h  make.sh       proff01.c pxxparse.c
Xdefs.h       lnk       makefile  proff02.c read.me
Xdostuff2.c   look.c        map.c         proffman.prf  see.me
Xeval.c       lookup.c  pinit.c       proffsym.new  stack.c
X
XThis file is see.me
X
XHow to make proff on the ST:
X
X    1) You will have to edit stdio.h supplied with the dev. system
Xto include the following lines at the bottom of stdio.h.
X
X    #ifdef DECL
X    #include <decl.h>
X    #endif
X
X    We do this so that when the pre-processor symbol DECL is
Xdefined the file decl.h gets included, and if it isn't then stdio.h
```

Xlooks exactly like it did before we added the lines. In decl.h we
Xdeclare all the commonly used function in C that do not returns the
Xtype int. This a important as in the Alcyon C compiler
X sizeof(int) != sizeof(int *). You may if you like include decl.h
Xelsewhere, but you will have to ensure that each of the modules
X(source files) has decl.h included. We found it convenient to put it
Xin stdio.h as above.
X
X   2) For those of you who have Micro C Shell and CC that i had
Xposted earlier to this newgroup, you can simply hit
X
X   make
X
Xat the Micro C Shell prompt.
X
X   3) For those who don't have Micro C Shell, but have CC, see
Xthe file make.sh, and enter those commands.
X
X   4) For those who don't have either, you will have to see
Xmake.sh and compile each C file such that DECL is defined, so you may
Xhave to change your normal batch file somewhat to have the
Xpreprocessor switch in there to define the symbol DECL.
X
XPlease note that make.sh was set up to have all the sources, objects
Xetc in the current directory. If you are compiling on floppies you may
Xhave to change that.
X
XThe file lnk contains the list of files to be linked, and is used with
Xlink68 as follows
X
X   link68 [com[lnk]]
X   relmod proff
X
XThe above process should yield proff.prg. If you want to use it from
Xthe desktop, rename it to proff.ttp.
X
X
XMaking Proff on the Vax
X   Simply hit
X   make
X
XMaking the users guide
X   On either the St or Vax hitting
X
X   proff -po8 proffman.prf proff.man
X
X   Will result in proff.man. (You may want to play with -po<n> to
Xget the correct left margin spacing for your printer).
X
X   If you have any problems/suggestions i may be reached at the
Xfollowing addresses:

YES!!! Try Xerox's Ventura Publisher software. It's great for creating
newspaper type documents with graphics included in or between the
columns. It displays the text and graphics right on the screen and
allows for all text and graphics manipulation stuff. You can even
magnify or shrink the graphics frames to suit the situation.

Mike

In article <2939@sdcc6.ucsd.EDU>, ix181@sdcc6.ucsd.EDU (John Ogawa) writes:
> I am an avid C++ fan who is about to get an Atari 1040ST and a C
> package. My question is: is there any way to get a C++ package for
> the 1040? Alternately, is there any C source code for CC that I can
> get my hands on?

   I am afraid this is unlikely. All C++ compilers I am aware of
(i.e. AT&T's) are actually fancy preprocessors that spit out rather
wild looking C. If CC is to work on an atari, your ATARI C compiler
must (and i mean MUST) be able to cope with *ARBITRARILY* long
identifiers.

   I am not aware of any C compiler for the atari ST that will suffice,
(my own Lattice C compiler nmormally uses only the first 8 characters,
and will in any event, use at most 32 characters of an identifier.
This is probably not enough for C++.)

                              M. Brinsmead @ Univewrsity of Calgary.

I just got this from CIS. In light of the large postings of late, it's
time has probably come. Give it to everyone you know, and we can all save
time and money when we upload/download stuff. I'll also be posting a
uuencoded/ARCd version of alite.prg in a few minutes...

-Rich

```
#! /bin/sh
# To extract, remove mail header lines and type "sh filename"
echo x - arc.doc
sed -e 's/^X//' > arc.doc << '!FaR!OuT!'
XIntroduction and short docs.
X          ARC (short for archive) is a file library and compression
X          utility.  It may be thought of as an improved version
X          of LU and SQUEEZE all rolled into one program.
X
X          ARC analyzes each file to see which of a number of
X          compression techniques will generate the smallest code.
X          The following estimates give the user a general idea of
X          how much compression may be gained by using ARC.
X
X                ARC Text -            45-55% reduction from original
X                SQUEEZED Text -       30-40% reduction
X
X                ARC Programs -        25-30% reduction
X                SQUEEZED Programs -   15-20% reduction
X
X                ARC Pictures -        45-55% reduction
X                SQUEEZED Pictures -   40-50% reduction
X                TINY Pictures -       40-50% reduction
X
X          The user should see that compressing files with ARC
X          will allow easier telecommunications by combining files
X          and shortening their transfer time.
X
X     Usage from TOS
X          - double-click-left on ARC.TTP icon
X          - observe OPEN APPLICATION menu for ARC.TTP parameters
X          - enter switch, archive name and file template
X            (ex: lh arc.arc *.*)
X          - hit return or click-left on OK box to begin execution
X          - "press any key to continue" after completion
X
X     History
X          ARC has been in use in the CP/M and MS-DOS world for many
X          years.  Thom Henderson developed the version which I
X          converted for use on the Atari ST.  I am not sure but he
X          may also be the original author.
```

X
X   It is important to note that no matter who developed this
X   program, ARC is based on the file compression theories
X   developed by Huffman, Welch, Knott, Knuth, and many other
X   scientists.
X
X   Bug Reports
X   Since I developed this version of ARC, I will be responsible
X   for any erroneous features. Please relay any problems with
X   a written discription of what happened and the .ARC file
X   which caused the problem to:
X
X   Harvey Johnson
X   2398 Oaklyn St NE
X   Palm Bay, FL 32907
X
X   - or -
X
X   QUILL BBS 305-724-2303
X
X
X   Future Products
X   It would be nice to have a version of ARC written to utilize
X   GEM. I would also like to write a picture display feature
X   that will show compressed pictures directly to the screen.
X   This will be useful in that ARC squeezes file 5 to 10% smaller
X   than TINY format. If anyone has the C source to dump NEO,
X   Degas, or other pictures to the screen please upload a copy
X   to QUILL BBS.
X
X   If you have any ideas for additional capabilities, then send
X   them to me with a detailed explanation. All thoughts are
X   welcome.
X
X   Donations
X   It would be nice to be supported if you think that ARC
X   is any good. Make no mistake, I did NOT write the original
X   version of ARC, but I have spent all my extra time for
X   two months making it a reality on the Atari ST.
X
X   As I do recieve contributions, I will consider improvements
X   more seriously. Any donations may be sent to address
X   specified in Bug Report section.
X
X   Thank you one and all in advance for considering this
X   request, but if you are like me (lazy) then I don't
X   really expect to ever see a single dime.
X
XARCHIVE (ARC.TTP)
X
X   Usage
X   arc {amdxelvth} <filename.ARC> [<filename> ...]
X

```
X               a   = add files to archive
X               m   = move files to archive
X               d   = delete files in archive
X               x,e = extract files from archive
X               l   = list files in archive
X               v   = verbose listing of files in archive
X               t   = test archive integrity
X               h   = hold screen before returning to Desktop
X
X     Description
X          This program is a general archive utility, and is
X          used to maintain an archive of files.  An "archive"
X          is a single file that combines many files, reducing
X          storage space and allowing multiple files to be
X          handled as one.
X     Switches
X
X          a - add files to archive.  This switch will force update
X              or addition the indicated reguardless of creation
X              time and date.
X
X          m - move files to archive.  Same as "a" switch except
X              that the files are deleted from the directory as
X              they are moved to the archive.
X
X          d - delete files in archive.  The files are lost forever
X              and the archive is recompacted to remove the data
X              for these files.
X
X          x,e - extract files from archive.  A copy of the files
X              in the archive are created in the current directory
X              in an uncompacted state.
X
X          l - list files in archive.  Limited information listing
X              of files contained in an archive.  Displays only the
X              filename.
X
X          v - verbose listing of files in archive.  Complete
X              information listing of files contained in an archive.
X              Displays the filename, original length, storage method,
X              storage factor (% savings), compacted size, date, time,
X              and CRC.
X
X          t - test archive integrity.  Check the archive to make sure
X              it does not have any bad files contained.
X
X          h - hold screen before returning to Desktop.  This switch
X              should be used whenever ARC is executed from the
X              Desktop, except in conjunction with file redirection.
X
X     Examples when executed from GEM Desktop:
X
X     ah FILES.ARC *.PRG      Creates a new archive file called FILES.ARC
```

```
X                           and puts all files ending in .PRG inside.
X
X     xh FILES.ARC *.*      Extracts all files from FILES.ARC.
X     xh FILES.ARC          ""
X     xh FILES              ""
X
X     xh FILES.ARC *.DOC    Extracts all files ending in .DOC.
X
X     In each case, the 'h' holds the display instead of immediately returning
X     to the GEM Desktop so you can view filenames, messages, etc.
X     These are just to help you get started.  ARC seems to be the most
X     reliable of the 'masher' programs and has the best overall size
X     reduction.

The following shar file contains:

```
     readme       obvious
     alite.uue   uuencoded ARC file
```

After running alite.uue through uudecode, you must use the ARC archive program I just posted to extract the files alite.prg, 1alite.sng, and 1alite.pic from alite.arc. I didn't write any of this stuff, I'm just distributing it. Enjoy.

-Rich

```
#! /bin/sh
# To extract, remove mail header lines and type "sh filename"
echo x - readme
sed -e 's/^X//' > readme << '!FaR!OuT!'
XHere is my test case for ARC.  Uudecode the file alite.uue and you'll end
Xup with alite.arc.  You may then use the "x" option in ARC to extract the
Xfollowing files:
X
X    alite.prg
X    1alite.sng
X    1alite.pic
X
XLet's all start using ARC and we can cut down considerably the amount of
Xtime and money we spend uploading/downloading software.
X
XAlite.prg was written by the fellows who brought you The Music Studio (tm)
Xand was posted nearly a year ago on CIS.  Basically, it is a MIDI/graphics
Xdemo with a pronounced yuletide flavor.  However, you can also use it to
Xplay all those *.sng files floating around out there.  To do so, you must
Xdo the following:
X
X    1) move the *.sng file to the same disk as alite.prg
X    2) rename the *.sng file 1alite.sng (or 2alite.sng, 3alite.sng,...)
X    3) make sure a corresponding 1alite.pic file is on the disk
X    4) execute alite.prg, the rest is easy
X
XI've included 1alite.sng and 1alite.pic in this posting to get you started.
X
